Introduction

THE IDEA TO DESIGN experiments systematically and with a view to their statistical analysis was first promoted by R. A. Fisher in his well known book "The Design of Experiments". Fisher also proposed the majority of the designs discussed in the present volume. Several designs of great importance, notably the quasifactorial designs and the incomplete balanced block designs, were discovered by F. Yates. R. A. Fisher's book, however, as well as other publications by R. A. Fisher and F. Yates and their school are not written for mathematicians. Thus the main emphasis is placed on the explanation of the procedure with little or no attention being paid to a mathematical formulation of the dissauliptions and to the principles of statistical inference which lead from the assumption to the statistical method. Moreover, also in many other important papers on analysis of variance and design of experiments proofs and derivations of formulae are barely sketched if not totally omitted. The present book tries to fill this gap and the main emphasis is therefore given to a rigorous mathematical treatment of the subject.

In writing this volume the author had in mind a reader with a mathematical background of a student, who majors in mathematics and is in his senior year. References are given whenever the text exceeds this background.

The book is designed to serve three different purposes. First, it was intended to enable a mature mathematician with no background in statistics to study the analysis of variance and analysis of variance designs within a reasonably short time. Secondly, it is intended to serve as a text book for a graduate or advanced undergraduate course in the subject. Finally, it is hoped that this book will be studied by practical experimenters and statisticians who wish to study the mathematical methods used in the analysis of variance and in the construction of

analysis of variance designs and are willing and able to expend the time and effort necessary for this purpose.

My thanks are due to the Iowa State College Press for their kind permission to include in this book the tables of the F-distribution of G. W. Snedecor's "Statistical Methods" and to the of L

I am indebted to Mr. Ransom Whitney who has assisted me in reading the manuscript and the proofs. I also wish to acknowledge my indebtedness to Professor W. G. Cochran for

CHAPTER I

Chi-square Distribution and Analysis of Variance Distribution

In this chapter certain fundamental concepts of the probability calculus are used. The reader who is not acquainted with these concepts should first acquire the necessary background by reading, for instance, Uspensky's, "Introduction to Mathematical Probability," Chapter XII. Sec. 8, example 3, Chapter XIII. Secs. 1-4 and 6, Chapter XV, Secs. 1-6.

Let x_1, \dots, x_N be normally and independently distributed variables with variances I and means 0. We wish to calculate the distribution of the expression

(1.1)
$$\chi^2 = x_1^2 + x_2^2 + \dots + x_2^2$$

$$www.dbraulibraiy.org/in$$

The joint distribution of x_1 , \cdots , x_N is given by the probability density function,

$$P(x_1, \dots, x_N) = \frac{1}{(2\pi)^{N/2}} \exp \left[-(x_1^2 + \dots + x_N^2)/2\right].$$

Hence the probability that

$$x^2 = x_1^2 + \cdots + x_N^2 \le R^2$$

is given by

$$\int_{S} \frac{1}{(2\pi)^{N/2}} e^{-\chi^2/2} dx_1 \cdot \cdot \cdot dx_N$$

where S is the sphere with radius R and center 0. The probability that

$$R^2 \le \chi^2 \le (R + \Delta R)^2$$

is, therefore, given by

$$C\int e^{-x^2/2} dx_1 \cdots dx_N$$

$$R^2 \le \chi^2 \le (R + \Delta R)^2$$

where C is a certain constant independent of R. If we denote the probability that $\chi^2 \leq R^2$ by $P(\chi^2 \leq R^2)$ we, therefore, have

$$\Delta[P(\chi^2 \le R^2)] = C e^{-\chi^{*2}/2} \Delta v$$

where $R^2 \le \chi^{*2} \le (R + \Delta R)^2$ and Δv is the volume of the spherical shell $R^2 \leq \chi^2 \leq (R + \Delta R)^2$. This volume is given by $\Delta v = C'R^{N-1}\Delta R$. If now ΔR approaches 0, we obtain

$$\frac{dP(\chi^2 \le R^2)}{dR} = C'' e^{-R^2/2} R^{N-1}.$$

Hence since $\chi^2 \geq 0$

$$C'R^{N-1}\Delta R$$
. If now ΔR approaches 0, we obtain
$$\frac{dP\left(\chi^2 \leq R^2\right)}{dR} = C'' e^{-R^2/2} R^{N-1}.$$
Let $\chi^2 \geq 0$

$$P(\chi^2 \leq R^2) = \int_0^R C'' e^{-\chi^2/2} \chi^{N-1} d\chi$$

$$= \int_0^{R^2} \overline{C}(\chi^2)^{(N-2)/2} e^{-\chi^2/2} d\chi^2.$$
Applied the points of χ^2 is therefore

The probability density of χ^2 is therefore,

$$P(\chi^2) = \overline{C}(\chi^2)^{(N-2)/2} e^{-\chi^2/2}$$
 for $\chi^2 \ge 0$
= 0 for $\chi^2 < 0$.

The constant \overline{C} still remains to be determined. We must have

$$\overline{C}$$
 still remains to be determined $\overline{C} \int_0^\infty (\chi^2)^{(N-2)/2} e^{-\chi^2/2} d\chi^2 = 1.$

Hence
$$\frac{1}{C} = \int_0^\infty (\chi^2)^{(N-2)/2} e^{-\chi^2/2} d\chi^2 = \int_0^\infty 2^{N/2} \left(\frac{\chi^2}{2}\right)^{(N-2)/2} e^{-\chi^2/2} d\left(\frac{\chi^2}{2}\right)$$

$$= 2^{N/2} \int_0^\infty x^{(N-2)/2} e^{-x} dx = 2^{N/2} \Gamma\left(\frac{N}{2}\right),$$

where

$$\Gamma(z) = \int_0^\infty x^{z-1} e^{-x} dx$$

is the well known I function.

Hence we finally have

(1.2)
$$P(\chi^2) = \frac{1}{2^{N/2} \Gamma(N/2)} (\chi^2)^{(N-2)/2} e^{-\chi^2/2}$$

The number N in this distribution is called the number of degrees of freedom.

This distribution is tabulated in almost every modern book on statistics for all degrees of freedom under 31. For larger values of N the quantity $(2\chi^2)^{\frac{1}{2}} - (2N-1)^{\frac{1}{2}}$ is approximately normally distributed with mean 0 and variance 1. For large values of N also $(\chi^2 - N)/(2N)^{\frac{1}{2}}$ is approximately so distributed.

If χ_1^2 has n_1 degrees of freedom and χ_2^2 has n_2 degrees of freedom, then χ_1^2 , (χ_2^2) is distributed as is the sum of n_1 , (n_2) independently and normally distributed variates. Hence we have

THEOREM 1.1: Let $\chi^{\lambda_{\gamma_{\gamma}}} \chi^{2}_{\lambda_{\gamma}}$ be independently distributed variables such that $\chi^{2}_{\lambda_{\gamma}}$ has the χ^{2} distribution with $n_{\lambda_{\gamma}}$ degrees of freedom then

$$\chi^2 = \chi_1^2 + \chi_2^2 + \cdots + \chi_s^2$$

has the χ^2 distribution with $n_1 + n_2 + \cdots + n_s = n$ degrees of freedom.

All of the theory of analysis and design of experiments which is presented in this book is based on the distribution of the ratio of two independent chi-square expressions. We therefore, proceed to derive this distribution.

Suppose that χ_1^2 is distributed according to 1.2 with n_1 degrees of freedom, and χ_2^2 with n_2 degrees of freedom and suppose that χ_1^2 and χ_2^2 are independently distributed. The joint distribution of χ_1^2 and χ_2^2 is then given by its density function

$$\begin{split} P(\chi_{\rm i}^2 \ , \, \chi_{\rm 2}^2) \ &= \frac{1}{2^{(n_1+n_2)/2} \Gamma(n_1/2) \Gamma(n_2/2)} \\ & \cdot (\chi_{\rm i}^2)^{(n_1-2)/2} (\chi_{\rm 2}^2)^{(n_1-2)/2} \ \exp \left[-(\chi_{\rm i}^2 \, + \, \chi_{\rm 2}^2)/2 \right]. \end{split}$$

We put

(1.3)
$$\frac{\chi_1^2}{\chi_2^2} = y, \quad \chi_1^2 + \chi_2^2 = z.$$

To every pair of values $y \ge 0$, $z \ge 0$, there exists one and only one pair of values $\chi_1^2 \ge 0$, $\chi_2^2 \ge 0$. We, therefore, obtain the probability density of y and z by transforming $P(\chi_1^2, \chi_2^2)$ by means of 1.3. From 1.3 we have

$$\begin{vmatrix} \frac{\partial \chi_1^2}{\partial y} & \frac{\partial \chi_1^2}{\partial z} \\ \frac{\partial \chi_2^2}{\partial y} & \frac{\partial \chi_2^2}{\partial z} \end{vmatrix} = \begin{vmatrix} \frac{z}{(1+y)^2} & \frac{y}{1+y} \\ \frac{-z}{(1+y)^2} & \frac{1}{1+y} \end{vmatrix} = \frac{z}{(1+y)^2}.$$

Hence the probability density of y and z is given by

$$\frac{1}{2\Gamma(n_1/2)\Gamma(n_2/2)} \frac{y^{(n_1-2)/2}}{(1+y)^{(n_1+n_2)/2}} \left(\frac{z}{2}\right)^{(n_1+n_2-2)/2} e^{-z/2}$$

for $z \geq 0$, $y \geq 0$,

and is 0 for either z < 0 or y < 0.

Integrating out with respect to z from 0 to ∞ , we obtain the density function of y

(1.4)
$$H(y) = \frac{\Gamma\left(\frac{n_1 + n_2}{2}\right)y \frac{n_1 - 2}{2}}{\Gamma\left(\frac{n_1}{2}\right)\Gamma\left(\frac{n_2}{2}\right)(1 + y) \frac{n_1 + n_2}{2}}.$$

Hence the probability that $y > \tilde{y} > 0$ is given by

The variable y was defined as the quotient of two independent chi-square expressions χ_1^2 and χ_2^2 with n_1 and n_2 degrees of freedom respectively. We shall consider the variable F given by

$$F = \frac{n_2}{n_1} \frac{\chi_1^2}{\chi_2^2}, \qquad \frac{n_1}{n_2} F = y.$$

The probability of obtaining an F larger or equal to \overline{F} is according to 1.5 and 1.4 given by

(1.6)
$$= \int_{F}^{\infty} \frac{\Gamma([n_{1} + n_{2}]/2)}{\Gamma(n_{1}/2)\Gamma(n_{2}/2)} \frac{(n_{1}/n_{2})^{n_{1}/2}F^{(n_{1}-2)/2}}{(1 + n_{1}F/n_{2})^{(n_{1}+n_{2})/2}} dF$$

$$= G(\overline{F}).$$
The values \overline{F} and $\overline{\overline{F}}$ for which
$$G(\overline{F}) = .05, \quad G(\overline{\overline{F}}) = .01.$$
have been tabulated by G. W. Snedecor in his books "Statistical Methods" and "Analysis of Variance and Covariance," which also contain a large collection of interesting applications of the Y^{2} and F statistic.

The values \overline{F} and $\overline{\overline{F}}$ for which

$$G(\overline{F}) = .05, \qquad G(\overline{\overline{F}}) = .0$$

have been tabulated by G. W. Snedecor in his books "Statistical Methods" and "Analysis of Variance and Covariance," which adilib. A silib. A si also contain a large collection of interesting applications of the

Matrices, Quadratic Forms, and the Multivariate Normal Distribution

A matrix is a rectangular array of coefficients

$$\left(\begin{matrix} \sigma_{11} \ , \ \cdots \ , \ \sigma_{1n} \\ \sigma_{m1} \ , \ \cdots \ , \ \sigma_{mn} \end{matrix}\right).$$

We shall denote such a matrix by (σ_{ij}) whenever the meaning of the numbers m and n will be clear from the context.

Consider a system of linear forms

$$(2.1) L_i = a_{i1}x_1 + \cdots + a_{in}x_n, i = 1, \cdots, m.$$

The matrix (a_i) ys called the matrix of the linear forms L_i in x_i , ..., x_n . Suppose now that the x_i are themselves linear forms in the variables y_1 , ..., y_n

$$(2.2) x_i = b_{i1}y_1 + \cdots + b_{is}y_s.$$

Then

$$L_i = \sum_{i=1}^n a_{ii} x_i = \sum_{i=1}^n \sum_{k=1}^s a_{ii} b_{ik} y_k = \sum_{k=1}^s y_k \sum_{i=1}^n a_{ii} b_{ik},$$

$$i=1, \cdots, m$$
.

The L_i are therefore linear forms in the variables y_1 , \cdots , y_s with the matrix (c_{is}) where

$$c_{ik} = \sum_{i=1}^{n} a_{ii}b_{ik}, \quad i = 1, \dots, m, k = 1, \dots, s.$$

It is therefore natural to define the product of two matrices by

(2.3)
$$(a_{ij})(b_{jk}) = \left(\sum_{j=1}^{n} a_{ij}b_{jk}\right).$$

Note that the product is only defined if (a_{ij}) has as many columns as (b_{ik}) has rows.

If we put

$$(L) = egin{pmatrix} L_1 \\ \cdot \\ \cdot \\ \cdot \\ L_m \end{pmatrix} \qquad (x) = egin{pmatrix} x_1 \\ \cdot \\ \cdot \\ \cdot \\ x_m \end{pmatrix}$$

we may rewrite (2.1) in matrix form as

(2.4)
$$(L) = (a_{ij})(x).$$

iplanior To a limited extent matrix notation and some of the most elementary theorems on matrices will be used in this book. If the reader is not familiar with the most elementary aspects of the theory of matrices, he should acquire the necessary background by reading, for instance, in A. A. Albert's book "Introduction to Algebraic Theories" Chapter 2 and Chapter 3, Section 1 to 11. Albert's book will be referred to as (AAA). We shall review here some elementary theorems which will be used in this chapter,

The multiplication of matrices is associative (AAA III. 2.) That is to say, if A, B, C are matrices such that (AB) and (BC) are defined then

$$(2.5) (AB)C = A(BC).$$

The multiplication of matrices is not commutative. That means that AB is not always the same as BA. In fact AB may be defined whilst BA is not.

The determinant of a square matrix $(a_{ij}) = A$ will be denoted by $|a_{ij}|$ or |A|. The equation

$$(2.6) |AB| = |A| |B|$$

holds (AAA, III, 5).

The matrix

(2.7)
$$\begin{cases} 10 \cdots 0 \\ 01 \cdots 0 \\ \vdots \\ 0 \cdots 1 \end{cases} = I$$

is called the unit matrix and it is easy to verify that AI = IA = A for every A for which IA and AI are defined.

If and only if $|A| \neq 0$ then A is called non singular and possesses an inverse A^{-1} for which (AAA, III, 6).

$$(2.8) AA^{-1} = A^{-1}A = I.$$

We shall always use the notation $(\sigma_{ij})^{-1} = (\sigma^{ij})$.

To every matrix $(a_{ii}) = A$ we can construct the transposed matrix A' by winter than ging rows and columns. One easily verifies the laws

verifies the laws
$$(2.9) \qquad (AB)' = B'A', \quad (AB)^{-1} = B^{-1}A^{-1}, \quad (A^{-1})' = A'^{-1}.$$

The symbol A' will be reserved in this book for the transposed of A.

We consider quadratic forms

(2.10)
$$Q = \sum_{i=1}^{n} \sum_{i=1}^{n} a_{ii}x_{i}x_{i}, \quad a_{ii} = a_{ii}.$$

We may write Q in matrix form

$$(2.11) Q = x'Ax,$$

where

$$A = (a_{ij}), \qquad x = \begin{pmatrix} x_i \\ \vdots \\ x_n \end{pmatrix}.$$

A is called the matrix of Q in the variables x_1, \dots, x_n .

Suppose that

$$x = Py, \qquad P = \begin{pmatrix} p_{11} & \cdots & p_{1m} \\ p_{n1} & \cdots & p_{nm} \end{pmatrix}, \qquad y = \begin{pmatrix} y_1 \\ \vdots \\ y_m \end{pmatrix}.$$

Then

$$(2.12) Q = x'Ax = y'P'APy.$$

Hence the matrix of Q in terms of the variables y_1 , \cdots , y_m is given by P'AP.

A quadratic form in x_1 , \cdots , x_n is called positive definite if it takes only positive values when the variables x_1 , \cdots , x_n , take real values not all equal to 0. It is called semi-definite when it takes only non-negative palves (positive and 0) for real x_1 , \cdots , x_n . Any quadratic form may, by a non singular transformation (AAA, III, 11.)

$$\overline{L}_i = \sum_{j=1}^n c_{ij} x_j, \qquad i = 1, \dots, n,$$

be transformed into

$$Q = \sum_{i=1}^{r} c_i \overline{L}_i^2, \qquad r \le n, \qquad c_i \ne 0.$$

The number r is called the rank of Q and is independent of the transformation provided it is non singular. The c_i must all be positive, if Q is positive semidefinite and the transformation $L_i = (c_i)^{\frac{1}{2}} \overline{L}_i$ leads to

$$Q = \sum_{i=1}^r L_i^2 .$$

If Q_1 has the rank n_1 and Q_2 the rank n_2 then $Q_1 + Q_2$ has at most the rank $n_1 + n_2$ for

$$Q_1 + Q_2 = \sum_{i=1}^{n_1} L_i^2 + \sum_{j=1}^{n_2} M_j^2.$$

Some of the L_i or M_i may be represented in terms of the others. Eliminating as many of them as possible we obtain

$$Q_1 + Q_2 = \sum_{i=1}^{n'} \sum_{j=1}^{n'} t_{ij} N_i N_j \qquad n' \leq n_1 + n_2$$

where the N_i are independent linear forms in the x's. Hence $Q_1 + Q_2$ has at most the rank $n_1 + n_2$. Hence we have

Lemma 2.1: The sum of the ranks of s quadratic forms is not smaller than the rank of their sum.

If x_1 , x_2 are two random variables with the means μ_1 and μ_3 then

$$E(x_1 - \mu_1)(x_2 - \mu_2) = \sigma_{12}$$
,

where E denotes the mathematical expectation, is called the covariance of x_{λ} and $x_{\alpha ullibrary.org.in}$

Let x_1 , \cdots , x_r be r jointly normally distributed variables with means 0 and covariance matrix (σ_{ij}) . Their density function is given by

$$(2.13) \quad P(x_1, \dots, x_r) = \frac{1}{(2\pi)^{r/2} \left| \sigma_{i,i} \right|^{1/2}} e^{-1/2} \sum_{i=1}^r \sum_{j=1}^r \sigma^{ij} x_i x_j ,$$

where the quadratic form in the exponent is positive definite.

The probability $P[(x_1, \dots, x_r \subset T]$ that the point (x_1, \dots, x_r) is in a subspace T of the r dimensional space is given by

(2.14)
$$P[(x_1, \dots, x_r) \subset T] = \int_T P(x_1, \dots, x_r) dx_1 dx_2 \dots dx_r.$$

If $E(x_i) = \mu_i \neq 0$ then we make the transformation $x_i' = x_i - \mu_i$. We shall formulate the results of this chapter for the case that $E(x_i) = 0$. It will be easy to find the proper formulation for the case $E(x_i) = \mu_i$.

We apply a non singular linear transformation (AAA, III, 6).

(2.15)
$$x_i = \sum_{i=1}^r p_{i,i} y_i, \quad i = 1, \dots, r.$$

The Jacobian determinant of this transformation is $|p_{ij}|$ and the new density function of the y's is therefore given by

$$(2.16) Q(y_1, \dots, y_r) = \frac{||P||}{(2\pi)^{r/2} ||\sigma_{ij}||^{1/2}} e^{-1/2} \sum \sigma^{*ij} y_i y_j,$$

where $(P) = (p_{ij}), (\sigma^{*ij}) = P'(\sigma^{ij})P$, and ||P|| denotes the absolute value of |P|. We may then write the constant term in (2.16) as

$$\frac{\mid\mid P\mid\mid}{(2\pi)^{r/2}\mid\sigma_{ij}\mid^{1/2}} = \frac{1}{(2\pi)^{\text{w/2}}\cdot \Pr_{(\sigma_{ij})} \operatorname{Toylogg}_{in}} \frac{1}{(2\pi)^{r/2}\mid\sigma_{ij}^{*}\mid} \,.$$

We see therefore that the y's are also jointly normally distributed with means 0 and covariance matrix

(2.17)
$$(\sigma_{ii}^*) = P^{-1}(\sigma_{ii})P'^{-1}.$$
 The matrix P is called orthogonal if

(2.18)
$$P^{-1} = P'$$
 or $P'P = PP' = I$.

In terms of the coefficients p_{ik} of P this means

(2.19)
$$\sum_{k=1}^{r} p_{ik} p_{tk} = \begin{cases} 1 & \text{if } i = l \\ 0 & \text{if } i \neq l. \end{cases}$$

If x_1, \dots, x_r are independently distributed with variance σ^2 then

(2.20)
$$\sigma_{ij} = \begin{cases} 0 & \text{for } i \neq j \\ \sigma^2 & \text{for } i = j \end{cases}$$

(2.21)

and it follows from (2.17) that if P is orthogonal

$$egin{aligned} (\sigma_{ii}^*) &= P' egin{pmatrix} \sigma^2 & \cdots & 0 \\ & \cdots & \ddots \\ & & \ddots & \ddots \\ 0 & \cdots & \sigma^2 \end{pmatrix} P \ & & & & & & & & & & & \\ & & P'P egin{pmatrix} \sigma^2 & \cdots & 0 \\ & \ddots & & \ddots \\ & & \cdots & \ddots \\ & & & \ddots & \ddots \\ & & & \ddots & \sigma^2 \end{pmatrix} &= egin{pmatrix} \sigma^2 & \cdots & 0 \\ & \ddots & \ddots & \ddots \\ & & \ddots & \ddots \\ & & \ddots & & \ddots \\ & & \ddots & & \sigma^2 \end{pmatrix} \end{aligned}$$

since a scalar matrix (AAA, II, 6, p. 30) commutes with ever other matrix. Hence we have

Lemma 2.2: If x_1 , \cdots , x_r are normally and independent distributed with means V and common variance σ^2 and if

$$(2.22) x_i = \sum_{i=1}^r p_{i,i} y_i, i = 1, 2 \cdots, r,$$

where $P = (p_{ij})$ is an orthogonal matrix then the y_i are independently and normally distributed all with the same variance σ

We proceed to prove

Lemma 2.3: Let

(2.23)
$$\sum_{i=1}^{n} x_{i}^{2} = Q_{1}(x) + \cdots + Q_{s}(x),$$

where $Q_i(x)$ is a quadratic form in x_1, \dots, x_r of rank n_i (AA. III, 11). Then there exists an orthogonal transformation

$$(2.24) x_i' = \sum_{k=1}^{n} p_{ik} x_k , i = 1, \cdots, n$$

such that

$$(2.25) Q_i = \sum_{k=n_1+\cdots+n_{l-1}+1}^{n_1+\cdots+n_l} x_k^{\prime 2}, i=1, \cdots, s$$

if and only if $n_1 + n_2 + \cdots + n_n = n$.

In the first place we have by Lemma 2.1

$$(2.26) n_1 + \cdots + n_* \geq n$$

since the rank of the left side of 2.23 is n.

Suppose first that there exists an orthogonal transformation fulfilling the conditions of Lemma 2.3. Then 2.24 and 2.25 imply

$$(2.27) n_1 + \cdots + n_s = n.$$

Now let $\sum_{i} n_{i} = n$. Since Q_{i} has the rank n_{i} there exist transformations

$$L_i = \sum_{k=1}^n p_{ik} x_k$$
(2.28)

$$j=n_1+\cdots+n_{i-1}+1,\cdots,n_1+n_2+\cdots+n_i$$

such that

(2.29)
$$Q_i = \sum_{i=n_1+\cdots+n_i=i+1}^{j=n_1+\cdots+n_i} L_i^2.$$

If the L_i were not independent, then the quadratic form $\sum Q_i \, = \, \sum_{i=1}^n \, L_i^2$

$$\sum Q_i = \sum_{j=1}^n L_i^2$$

would have a rank smaller than n. But this is impossible on account of 2.23. Hence the L_i are independent. We may regard therefore the transformation (2.28) as one non singular transformation with $j = 1, \dots, n$. Putting

$$L = \begin{pmatrix} L_1 \\ \cdot \\ \cdot \\ L_n \end{pmatrix}, \qquad X = \begin{pmatrix} x_1 \\ \cdot \\ \cdot \\ \cdot \\ x_n \end{pmatrix}, \qquad P = (p_{ij})$$

we may therefore write L = PX, where $P = (p_{ij})$ is non singular. Since

$$Q = \sum_{i=1}^{n} x_i^2 = \sum_{i=1}^{r} Q_i = \sum_{i=1}^{n} L_i^2,$$

we have

$$X'IX = L'P'^{-1}IP^{-1}L.$$

But $P'^{-1}IP^{-1}$ is the matrix of Q as a form in L_1 , \cdots , L_n and this matrix is the unit matrix. Hence

$$P'^{-1}P^{-1} = I.$$

 P^{r-1} and therefore also P are thus orthogonal matrices and Lemma 2.3 is proved.

THEOREM 2.1: Let x_1, \dots, x_n be normally and independently distributed variables with variance 1. Let

distributed variables with variance 1. Let
$$(2.29) Q_1 + \cdots + Q_s = \sum_{i=1}^{s-n} x_i^2,$$
where Q_i is a quadratic form of rank n_i .

where Q_i is a quadratic form of rank n_i .

The Q, are independently distributed and Q, has this square distribution with not degrees of freedom if and only if

$$(2.30) n_1 + n_2 + \cdots + n_s = n.$$

Suppose first that the Q_i are independently distributed and that Q_i has the χ^2 distribution with n_i degrees of freedom. Then by Theorem 1.1 $Q_1 + \cdots + Q_s$ has the χ^2 distribution with $n_1 + n_2 + \cdots + n_s$ degrees of freedom but on account of (2.29) it has also the χ^2 distribution with n degrees of freedom and (2.30) follows.

On the other hand suppose that $n_1 + \cdots + n_r = n$. Then by Lemma 2.3 there exists an orthogonal transformation

$$x_i = \sum p_{ik} x_k'$$

such that

$$Q_i = \sum_{j=n_1+\cdots+n_{i-1}+1}^{n_1+\cdots+n_i} x_k'^2.$$

But by Lemma 2.2 the quantities x_i' are normally and independently distributed variables with means 0 and variance 1. Hence the Q_i are independently distributed and Q_i has by our results in chapter 1 the χ^2 distribution with n_i degrees of freedom. This proves Theorem 2.1.

Corollary to Theorem 2.1: Let x_1, \dots, x_n be normally and independently distributed with means 0 and variance σ^2 and let $Q_i(i=1,\dots,s)$ be s quadratic forms in x_1,\dots,x_n with ranks n_1,\dots,n_s and

$$Q_1 + Q_2 + \cdots + Q_s = Q = \sum_{i=1}^n x_i^2$$

then n_i/n_i Q_i/Q_i has the F distribution with n_i and n_i degrees of freedom respectively.

The variables x_1/σ , \cdots , x_n/σ are normally distributed with variance 1 and means 0. Therefore Q_i/σ^2 has by Theorem 2.1 the χ^2 distribution with n_i degrees of freedom and the corollary follows from our results in Chapter blary.org.in

The corollary to Theorem 2.1 is of importance in the analysis

The corollary to Theorem 2.1 is of importance in the analysis of variance. Theorem 2.1 and its corollary were first formulated by W. G. Cochran.

CHAPTER III

Analysis of Variance in a One Way Classification

Let X_1, \dots, X_s be s normally and independently distributed variates with common variance σ^2 , and let X_s have the mean value μ_i . For instance, consider s different races of cattle and let X_s be the birth weight of calves of the *i*th race. We wish to test the hypothesis that $\mu_i = \dots = \mu_s = \mu$.

Suppose a random sample is taken of n_1 individuals of X_1 , n_2 of X_2 , \cdots , n_n of X_n . The values obtained are x_{11} , \cdots , x_{1n_1} , from the first variate x_{21} , \cdots , x_{2n_1} from the second and so forth. Let

$$x_{i,db} = x_{i,1} + x_{i,2} + x_{in} + x_{in_i}$$

$$n_i$$

be the mean of the ith sample and let

$$x = \frac{\sum_{i} \sum_{j} x_{ij}}{n_{i}}, \quad n = n_{1} + \cdots + n_{s},$$

where \sum_{i} denotes summation over all values of i, be the total mean.

We shall first prove the following identity. Let α_1 , \cdots α_t be t numbers,

$$\alpha = \frac{\alpha_1 + \cdots + \alpha_t}{t}$$

their mean then

(3.1)
$$\sum_{i} \alpha_{i}^{2} = \sum_{i} (\alpha_{i} - \alpha)^{2} + t\alpha^{2}.$$

Proof: We have

$$\sum_{i} \alpha_{i}^{2} = \sum_{i} (\alpha_{i} - \alpha + \alpha)^{2}$$

$$= \sum_{i} (\alpha_{i} - \alpha)^{2} + 2\alpha \sum_{i} (\alpha_{i} - \alpha) + t\alpha^{2}$$

but

$$\sum_{i} (\alpha_{i} - \alpha)\alpha = \alpha \sum_{i} (\alpha_{i} - \alpha) = \alpha(\sum_{i} \alpha_{i} - \sum_{i} \alpha_{i}) = 0$$

which proves (3.1). We apply (3.1) to $\sum_i x_{ij}^2$ and obtain

(3.2)
$$\sum_{i} (x_{ii})^{2} = \sum_{i} (x_{ii} - x_{i})^{2} + n_{i}x_{i}^{2}.$$

Thus

Thus
$$(3.3) \qquad \sum_{i} \sum_{i} x_{ii}^{2} = \sum_{i} \sum_{i} (x_{ii} - x_{i})^{2} + \sum_{i} n_{i} x_{i}^{2}.$$
Next we apply (3.1) to $\sum_{i} n_{i} x_{i}^{2}$ whereby we consider $n_{i} x_{i}^{2}$

Next we apply (3.1) to $\sum_i n_i x_i^2$ whereby we consider $n_i x_i^2$ as the sum of n_i quantities. Then x is the mean of all the nquantities x_i and by (3.1)

(3.4)
$$\sum_{i} n_{i} x_{i}^{2} = \sum_{i} n_{i} (x_{i} - x)^{2} + n x^{2}.$$

Substituting (3.4) into 3.3 we finally have

(3.5)
$$\sum_{i} \sum_{i} x_{ij}^{2} = \sum_{i} \sum_{j} (x_{ij} - x_{i})^{2} + \sum_{i} n_{i} (x_{i} - x)^{2} + nx^{2}.$$

We shall always write E(x) for the mathematical expectation of a random variable x. We put $E(x_i) = \mu_i$ and $1/n \sum_i n_i \mu_i = \mu_i$ then $(x_{ij} - x_i) = (x_{ii} - \mu_i) - (x_i - \mu_i)$ and by (3.1)

$$\sum_{i} \sum_{i} (x_{ii} - x_i)^2$$

(3.6)

$$= \sum_{i} \sum_{i} (x_{ii} - \mu_{i})^{2} - \sum_{i} n_{i} (x_{i} - \mu_{i})^{2}.$$

By assumption $E(x_{ij} - \mu_i)^2 = \sigma^2$ independent of i and j. Since $\sigma_{x_i}^2 = \sigma^2/n_i$ we obtain from (3.6)

$$E[\sum_{i} \sum_{i} (x_{ii} - x_{i})^{2}] = n\sigma^{2} - s\sigma^{2} = (n - s)\sigma^{2}.$$

On the other hand

(3.7)
$$\sum_{i} n_{i}(x_{i} - x)^{2} = \sum_{i} n_{i}[(x_{i} - \mu) - (x - \mu)]^{2}$$
$$= \sum_{i} n_{i}(x_{i} - \mu)^{2} - n(x - \mu)^{2}.$$

But

$$(x_i - \mu)^2 = (x_i - \mu_i)^2 + (\mu_i - \mu)^2 + 2(x_i - \mu_i)(\mu_i - \mu).$$

Hence

(3.8)
$$E(x_i - \mu)^2 = E(x_i - \mu_i)^2 + (\mu_i - \mu)^2 + 2(\mu_i - \mu)E(x_i - \mu_i)$$
$$= \frac{\sigma^2}{\pi} + (\mu_i - \mu)^2.$$

Therefore from (3.7)

$$= \frac{\sigma^2}{n_i} + (\mu_i - \mu)^2.$$
Therefore from (3.7)
$$E[\sum_i n_i (x_i - x)^2] = s\sigma^2 + \sum_i n_i (\mu_i - \mu)^2 - \sigma^2$$
(3.9)
$$= (s - 1)\sigma^2 + \sum_i n_i (\mu_i - \mu)^2.$$
Thus whilst $E[\sum_i \sum_i \sum_i (x_i) - x_i]^2$ is an unbiased estimat

Thus whilst $E[\sum_{i}^{\text{dhr}} \sum_{i}^{\text{olighar}} (x_{ij} - x_{i})^{i}]$ is an unbiased estimate of $(n-s)\sigma^2$ regardless of any hypothesis about the μ_i we see from (3.9) that $\sum_{i} n_{i}(x_{i} - x)^{3}$ is an unbiased estimate of σ^2 only if $\mu_1 = \mu_2 = \cdots = \mu_s$. Otherwise its expectation is larger than σ^2 . That is to say; if the hypothesis $\mu_1 = \mu_2 =$ $\cdots = \mu_{\bullet} = \mu$ is incorrect the ratio

(3.10)
$$F = \frac{n-s}{s-1} \frac{\sum_{i} n_{i}(x_{i}-x)^{2}}{\sum_{i} \sum_{i} (x_{ij}-x_{i})^{2}}$$

will tend to be large. It seems therefore, reasonable to use this ratio F as a statistic for testing the hypothesis $\mu_1 = \mu_2 =$ $\cdots = \mu_* = \mu$ and to reject this hypothesis on the level of significance α if this ratio is larger than could be expected by chance with probability a. A theoretical justification for using this F ratio will be given in chapters 4 and 6.

We shall now show that the statistic redefined by (3.10) has the F distribution of Chapter 1 with (s-1) and (n-s)degrees of freedom. We first substitute in (3.5) $x_{ij} - \mu$ for x_{ii} . Then

$$(3.11) \sum_{i} \sum_{j} (x_{ij} - \mu)^{2} = \sum_{i} \sum_{j} (x_{ij} - x_{i})^{2} + \sum_{j} n_{i}(x_{i} - x)^{2} + n(x - \mu)^{2}.$$

We now put

$$\sum_i \sum_i (x_{ii} - x_i)^2 = Q_1$$
 of rank m_1 , $\sum_i n_i (x_i - x)^2 = Q_2$ of rank m_2 , $n(x - \mu)^2 = Q_3$ of rank m_3 . In of squares of the linear forms $L_{ij} = (x_{ij} - x_i)$ by L_{ij} there exist s obviously independent relations

 Q_i is a sum of squares of the linear forms $L_{ij} = (x_{ij} - x_i)$. Between the L_{ii} there exist s obviously independent relations $\sum_i L_{ii} = 0, i = 1, \cdots$, s. Since we may put

$$L_{ini} = -\sum_{i=1}^{n_i \sum_{i=1}^{l} \bigvee w. dbraulibrary.org.in} L_{ii}$$
 , $i = (1, \cdots, s)$,

and thus write Q_1 as a quadratic form in (n - s) linear forms, it follows that Q_1 has at most the rank n-s. Similarly Q_2 has at most the rank s = 1 and Q_3 has obviously the rank 1. But

(3.13)
$$(n-s) + (s-1) + 1 = n.$$

It follows thus from (3.11) and Lemma 2.1 of Chapter 2 that $m_1 = n - s$, $m_2 = s - 1$, $m_3 = 1$. If $\mu_1 = \mu_2 = \cdots = \mu$ then the $(x_i, -\mu)$ are by assumption normally and independently distributed with common variance σ^2 . By the corollary to theorem 2.1

$$(3.14) \qquad \qquad \frac{n-s}{s-1} \frac{Q_2}{Q_1}$$

has the F distribution with n = s and s = 1 degrees of freedom respectively.

If the quantities $\mu_i - \mu$ are not all equal to 0 then \sum $n_i(x_i - x)^2/\sigma^2$ does not have the χ^2 distribution although $\sum_{i} \sum_{i} (x_{ij} - x_{i})^{2}/\sigma^{2} = \overline{Q}_{1}$ still has. This may be seen by applying (3.1) to obtain

$$\overline{Q}_{i}' = \sum_{i} (x_{ij} - \mu_{i})^{2} = \sum_{i} (x_{ij} - x_{i})^{2} + n_{i}(x_{i} - \mu_{i})^{2},$$

$$= \overline{Q}_{i} + n_{i}(x_{i} - \mu_{i})^{2},$$
(3.15)

 $i = (1, \cdots, s).$

The rank of \overline{Q}_i is at most $n_i - 1$ and it follows from Lemma 1 in Chapter 2 that \overline{Q}_i has exactly the rank $n_i - 1$. From Theorem 2.1 and the independence of the x_i , it thus follows that

(3.15)
$$\sum_{i} \sum_{j} (x_{ij} - x_{i})^{2} / \sigma^{2}$$

has the χ^2 distribution with n-s degrees of freedom irrespective of any hypothesis about the μ_1 .

In the comparison of classes it is very often desirable to test the significance of differences between class means. Suppose we wish to test whether there is a difference between the means of the *i*th and the *j*th class. We put

$$\frac{n_i x_i + n_i x_i}{n_i + n_i} = x'$$

and consider the expression

$$n_i(x_i - x)^2 + n_i(x_i - x)^2 = n_i(x_i - x')^2$$

(3.16)

$$+ n_i(x_i - x')^2 + (n_i + n_i)(x' - x)^2.$$

It follows that

$$\sum_{k} n_{k}(x_{k} - x)^{2} = \sum_{\substack{i \neq i \\ 1 \neq i}} n_{i}(x_{i} - x)^{2} + n_{i}(x_{i} - x')^{2} + n_{i}(x_{i} - x')^{2} + n_{i}(x_{i} - x')^{2} + n_{i}(x_{i} - x')^{2} + n_{i}(x_{i} - x')^{2}.$$

Substituting (3.17) in (3.11) we have, on account of (3.12),

$$\sum_{i} \sum_{j} (x_{ij} - \mu)^{2} = Q_{1} + \sum_{\substack{i \neq j \\ i \neq j}} n(x_{i} - x)^{2} + n_{i}(x_{i} - x')^{2}$$
(3.18)

$$+ n_i(x_i - x')^2 + (n_i + n_i)(x' - x)^2 + n(x - \mu)^2$$
.

The rank of

$$\sum_{\substack{l \neq i \\ l \neq j}} n_l (x_i - x)^2 + (n_i + n_j)(x' - x)^2$$

is at most s-2. The rank of

$$n_i(x_i - x')^2 + n_i(x_i - x')^2 = \frac{n_i n_i}{n_i + n_i}(x_i - x_i)$$

is one; hence by the corollary to Theorem 2.1

(3.19)
$$F = \frac{n-s}{1 \text{www.dbraultbrary.corg.in}} \frac{(x_i - x_j)^2}{\text{dbraultbrary.corg.in}}$$

has the F distribution with 1 and n-s degrees of freedom respectively. We have shown before that Q_1 is not affected if $\mu_i \not= \mu_i$ but

$$E(x_i - x_i)^2 = E\{[(x_i - \mu_i) - (x_i - \mu_i) + (\mu_i - \mu_i)]^2\}$$

$$= \frac{n_i + n_i}{n_i n_i} \sigma^2 + (\mu_i - \mu_i)^2.$$

Hence $(x_i - x_i)^2$ will tend to be large if μ_i differs substantially from μ_i . It seems, therefore, reasonable to use the F statistic in (3.19) to test the hypothesis $\mu_i = \mu_i$.

CHAPTER ĮΥ

Likelihood Ratio Tests and Tests of Linear Hypothesis

Let the variable vector $x = (x_1, \dots, x_n)$ have the distribution function $f(x, \theta_1, \dots, \theta_k)$ depending on k parameters θ_1 , \cdots , θ_k . We may know that θ_1 , \cdots , θ_k satisfy certain relations.

relations.
$$g_i(\theta_1, \cdots, \theta_k) = 0, \quad i = 1, \cdots, s,$$

$$(4.1) \qquad \qquad 0 \le s \le k.$$
We wish to test the hypothesis that $\theta_i, \cdots, \theta_k$ satisfy additional relations ulibrary organ

additional relations with the relationship additional relationship representations and relationship relations

$$(4.2) g_{j}(\theta_{1}, \dots, \theta_{k}) = 0, j = s + 1, \dots, s + r, 0 < r \leq k - s.$$

Let x_1, \dots, x_n be an independent sample of nx's. The distribution in the sample space is then given by its probability density

$$(4.3) p(x_1, \dots, x_n) = \prod_i f(x_i, \theta_1, \dots, \theta_k).$$

For a given sample x_1, \dots, x_n the density becomes a function $p(\theta_1, \dots, \theta_k)$ of $\theta_1, \dots, \theta_k$. Let $\hat{\theta}_1, \dots, \hat{\theta}_k$ be a set of values for which $p(\theta_1, \dots, \theta_k)$ is maximized under the restrictions (4.1). We call $\hat{\theta}_1$, \cdots , $\hat{\theta}_k$ the maximum likelihood estimates of θ_1 , ..., θ_k . Maximum likelihood estimates may also be obtained under the restrictions (4.1) and (4.2) and these estimates will be denoted by $\hat{\theta}'_1$, \cdots , $\hat{\theta}'_k$. Clearly

$$(4.4) p(\hat{\theta}_1, \dots, \hat{\theta}_k) \geq p(\hat{\theta}'_1, \dots, \hat{\theta}'_k).$$

The ratio

(4.5)
$$\frac{p(\hat{\theta}'_1, \dots, \hat{\theta}'_k)}{p(\hat{\theta}_1, \dots, \hat{\theta}_k)} = \lambda$$

is called the likelihood ratio for the hypothesis (4.2). The use of λ as a statistic to test the hypothesis (4.2) can be justified on the basis of certain criteria (see f.i. A. Wald: Tests of statistical hypothesis concerning several parameters, when the number of observations is large. Trans. Am. Math. Sec. 54; pp. 426-482). We shall at this point advance only an intuitive argument. Suppose that our hypothesis is false, then λ would tend to be smaller than if the hypothesis were true. It seems, therefore, reasonable to use λ as a statistic to test the hypothesis (4.2) and to reject it on the level of significance α if $\lambda < \lambda_0$ where λ_0 is chosen so that $P(\lambda < \lambda_0 \mid 4.2) = \alpha$ where $P(E \mid H)$ denotes the probability that the event E will happen computed under the hypothesis H.

All the tests which will be discussed in this book are tests of linear hypotheses. We consider a set of N random variables y_1 , \cdots , y_N and put $E(y_{aw} - \mathbf{d}_{bwa}) + \mathbf{d}_{bwa} + \mathbf{d}_{bwa$

- 1) The y_α are normally and independently distributed and their variances are equal.
- 2) The μ_{α} are linear functions of p parameters β_1 , \cdots , β_r , $p \leq N$.

and the rank (A.A.A. II 7) of the matrix (g_{ia}) is equal to p.

Eliminating the β_i from (4.6) we see that the assumption 2 is equivalent to assuming that the μ_{α} satisfy N-p linear restrictions:

$$\sum_{\alpha} \lambda_{k\alpha} \mu_{\alpha} = 0, \qquad k = 1, \cdots, N - p,$$

(4.6')

$$rank (\lambda_{ka}) = N - p.$$

The hypothesis we wish to test is that the β_i satisfy s independent linear restrictions.

$$(4.7) \qquad \sum_{i} k_{ii}\beta_{i} = 0, \qquad i = 1, \cdots, s, \qquad s \leq p.$$

The hypothesis can, by eliminating the β_i from (4.6) and (4.7), also be written as

$$\sum_{\alpha=1}^{N} \rho_{k\alpha} \mu_{\alpha} = 0, \qquad k = 1, \dots, s,$$

$$\begin{pmatrix} \lambda_{11} & \cdots & \lambda_{1N} \\ \vdots & \vdots & \vdots \\ \lambda_{N-p,1} & \cdots & \lambda_{N-p,N} \\ \rho_{11} & \cdots & \rho_{1N} \end{pmatrix} = N - p + s.$$

$$\begin{pmatrix} \lambda_{11} & \cdots & \lambda_{N-p,N} \\ \vdots & \vdots & \vdots \\ \rho_{s1} & \cdots & \rho_{sN} \end{pmatrix}$$

$$= N - p + s.$$

$$\begin{pmatrix} \lambda_{11} & \cdots & \lambda_{N-p,N} \\ \vdots & \vdots & \vdots \\ \rho_{s1} & \cdots & \rho_{sN} \end{pmatrix}$$

According to description 1 the joint density function of y_1, \dots, y_N is given by

$$y_1$$
, ..., y_N is given by
$$\frac{1}{\sigma^N (2\pi)^{N/2}} \exp\left[-\frac{1}{2} \sum_{\alpha} \frac{(y_{\alpha} - \mu_{\alpha})^2}{\sigma^2}\right].$$

We now compute the likelihood ratio. The expression (4.8) is maximized if we minimize

$$(4.9) \qquad \sum_{\alpha} (y_{\alpha} - \mu_{\alpha})^2 = \sum_{\alpha} (y_{\alpha} - g_{1\alpha}\beta_1 - \cdots - g_{\nu\alpha}\beta_{\nu})^2.$$

Let b_1 , \cdots , b_p be the maximum likelihood estimates of β_1 , \cdots , β_p . We put

$$(4.10) Q_a = \sum_{\alpha} (y_{\alpha} - g_{1\alpha}b_1 - \cdots - g_{n\alpha}b_n)^3.$$

Similarly the maximum likelihood estimate of σ is obtained as

$$\hat{\sigma}^2 = \frac{Q_a}{N} .$$

The maximum likelihood under the assumptions then becomes

(4.12)
$$\Omega_{\rm max} = \left(\frac{N}{2\pi Q_{\rm s}}\right)^{N/2} e^{-N/2}.$$

Let Q, be the minimum of

$$\sum (y_{\alpha} - \mu_{\alpha})^2 = \sum_{\alpha} (y_{\alpha} - g_{1\alpha}\beta_1 - \cdots - g_{p\alpha}\beta_p)^2$$

obtained under the restrictions (4.7) imposed by the hypothesis. The maximum likelihood under the restrictions (4.6) and (4.7) then becomes

(4.13)
$$\omega_{\max} = \left(\frac{N}{2\pi Q}\right)^{N/2} e^{-N/2}.$$

Hence the likelihood ratio is given by

$$\lambda = \left(\frac{Q_{\alpha}}{Q_{r}}\right)^{N/2}.$$

as given by $\lambda = \left(\frac{Q_{\alpha}}{Q_{r}}\right)^{N/2}.$ The may inster the rice for In testing a hypothesis we may instead of a given test function like \(\lambda\) take any monotonic function of it. Hence instead of $(Q_a/Q_r)^{N/2}$ we may take as a test function Q_r/Q_a or

(4.15)
$$F = \frac{N - p}{s} \frac{Q_r - Q_o}{Q_a}.$$

We decided to reject (4.7) if $\lambda < \lambda_0$ whereby λ_0 is determined so that $P(\lambda < \lambda_0 \mid 4.7) = \alpha$. Since F is a monotonically decreasing function of λ we obtain a test equivalent to the likelihood ratio test if we reject (4.7) whenever $F \geq F_0$ where $P(F \geq F_0 \mid 4.7) = \alpha.$

We proceed to derive the distribution of the ratio (4.15) and we shall show that it has the F distribution of Chapter I with s and N - P degrees of freedom respectively. We first prove:

Lemma 4.1: Let

(4.16)
$$\sum_{i} a_{ii} \mu_{i} = 0, \quad i = 1, \dots, k$$

be k linearly independent linear restrictions on the values μ_1 , \cdots , μ_N . Then there exists a system of restrictions

(4.16')
$$\sum_{i} b_{ii}\mu_{i} = 0, \quad i = 1, \cdots k$$

such that the restrictions $\sum_i a_{i,i}\mu_i = 0$, $i = 1, \dots, l \leq k$ are equivalent to the restrictions $\sum_i b_{ij}\mu_i = 0, i = 1, \cdots, l \leq k$ and such that the rows of the matrix (b_{ij}) are orthogonal to each other, that is to say such that

(4.17)
$$\sum_{\alpha=1}^{\alpha=N} b_{i\alpha}b_{i\alpha} = \delta_{ii} = \begin{cases} 1 & \text{if } i=j\\ 0 & \text{if } i \neq j. \end{cases}$$

Proof: We put

$$b_{1i} = \frac{a_{1i}}{(\sum a_{1i}^2)^{1/2}}$$

The put
$$b_{1i} = \frac{a_{1i}}{(\sum a_{1j}^2)^{1/2}}$$

$$b_{2i}^* = a_{2i} + \lambda b_{1i} \quad \text{where} \quad \lambda = \sum_i b_{1i} a_{2i}$$

$$\sum_i b_{1i} b_{2i}^* = \sum_j b_{1i} a_{2i} - \lambda = 0.$$
In put
$$b_{2i} = \frac{b_{2i}^*}{(\sum_i b_{2i}^{*2})^{1/2}}$$
possible since

then

$$\text{ww.} \sum_{i} b_{ia} b_{ib} b_{ib} = r \sum_{i} b_{ia} b_{ib}, \quad -\lambda = 0.$$

We then put

we then put
$$b_{zi}=\frac{b_{zi}^*}{(\sum_i b_{zi}^{*2})^{\frac{1}{2}}})^{\frac{1}{2}}$$
 This is possible since
$$\sum_i b_{zi}^{*2}>0.$$

$$\sum_i b_{2i}^{*2} > 0.$$

Otherwise the second equation would be a multiple of the first, contradicting the assumption of independence of the system (4.16). The systems

$$\sum_{i} a_{ii}\mu_{i} = 0, \qquad \sum_{i} b_{ii}\mu_{i} = 0, \qquad i = 1, 2$$

are obviously equivalent. Suppose now that we have succeeded in constructing a system

$$(4.18) \qquad \sum_{\alpha} b_{i\alpha}\mu_{\alpha} = 0, \qquad i = 1, \cdots, l < k$$

fulfilling (4.17), which is equivalent to

$$\sum_{\alpha} a_{i\alpha} \mu_{\alpha} = 0, \qquad i = 1, \cdots, l < K.$$

We put

$$b_{l+1\alpha}^* = a_{l+1\alpha} - \lambda_1 b_{1\alpha} - \cdots - \lambda_l b_{l\alpha},$$

where

$$\lambda_i = \sum_{\alpha} a_{i+1\alpha} b_{i\alpha}$$
, $i = 1, \dots, l$,

then.

$$\sum_{\alpha} b_{l+1\alpha}^* b_{i\alpha} = \sum_{\alpha} a_{i+1\alpha} b_{i\alpha} - \sum_{\alpha} \sum_{i=1}^{l} \lambda_i b_{i\alpha} b_{i\alpha},$$

$$j = 1, \dots, l.$$
4.17) is valid for $i, j \leq l$ we have
$$\sum_{\alpha} b_{i,\alpha}^* b_{i,\alpha} = \sum_{\alpha} a_{i,\alpha} b_{i,\alpha} - \lambda_i = 0$$

$$j = 1, \dots, l$$
.

Since (4.17) is valid for $i, j \leq l$ we have

$$\sum_{\alpha} b_{i+1\alpha}^* b_{i\alpha} = \sum_{\alpha} a_{i+1} b_{i\alpha} - \lambda_i = 0.$$
www.dbraulibrary.org.in

Now $\sum_{\alpha} b_{l+1}^{*2} > 0$ since otherwise the (l+1)st equation would be a linear combination of the first l equations, contradicting the assumption of independence of (4.16). We then have only to put

$$b_{l+1\,\alpha} = (\frac{b_{l+1\,\alpha}^*}{\sum_{\alpha} b_{l+1}^{*2}})^{1/2}$$

to obtain the (l+1)st equation of the system $\sum_{\alpha} b_{i\alpha}\mu_{\alpha} = 0$ fulfilling (4.17) and equivalent to the initial equations of (4.16). The process may be continued until all k rows of (4.16') are obtained.

Applying Lemma 4.1 to the restrictions imposed on the μ_{α} by the hypothesis and the assumptions of the linear hypothesis we may assume that the rows of (4.6') and (4.7') are normalized and orthogonal, that is to say that

$$\sum_{\alpha} \lambda_{i\alpha} \lambda_{j\alpha} = \sum_{\alpha} \rho_{i\alpha} \rho_{j\alpha} = \delta_{ij} = \begin{cases} 0 & \text{for } i \neq j \\ \\ 1 & \text{for } i = j. \end{cases}$$

$$\sum_{\alpha} \rho_{i\alpha} \lambda_{j\alpha} = 0.$$

If p > s we form an additional row τ_{11} , \cdots , τ_{1n} such that

$$\sum_{i} \lambda_{i\alpha} \tau_{1\alpha} = 0, \qquad i = 1, \dots, p$$

$$\sum_{i} \rho_{i\alpha} \tau_{1\alpha} = 0, \qquad i = 1, \dots, s.$$

This is possible since N - p + s < N equations in N unknowns have a non trivial solution. Thus continuing we finally obtain an orthogonal matrix

$$(4.19) \begin{cases} \lambda_{11} , \cdots , \lambda_{1N} \\ \vdots \\ \lambda_{N-p1} , \cdots , \lambda_{N-pN} \\ \rho_{11} , \cdots , \rho_{1N} \\ \vdots \\ \vdots \\ \rho_{s1} , \cdots , \rho_{sN} \\ \tau_{11} , \cdots , \tau_{1N} \\ \vdots \\ \vdots \\ \vdots \\ \tau_{p-s1} , \cdots , \tau_{p-sN} \end{cases}.$$

We now put

$$y_i^* = \sum_{\alpha} \lambda_{i\alpha} y_{\alpha} \quad \text{for } i = 1, \dots, N - p;$$

$$(4.20) \quad y_{N-p+k}^* = \sum_{\alpha} \rho_{k\alpha} y_{\alpha} \quad \text{for } k = 1, \dots, s;$$

$$y_{N-p+k+1}^* = \sum_{\alpha} \tau_{l\alpha} y_{\alpha} \quad \text{for } l = 1, \dots, p - s.$$

Let
$$E(y_{\alpha}^*) = \mu_{\alpha}^*$$
. Then

$$\mu_{\alpha}^* = \sum_i \lambda_{\alpha i} \mu_i$$
, $\alpha = 1, \dots, N - p$;

(4.21)
$$\mu_{N-p+\beta}^* = \sum_i \rho_{\beta i} \mu_i , \qquad \beta = 1, \cdots, s;$$

$$\mu_{N-p+s+\gamma}^* = \sum_i \tau_{\gamma i} \mu_i$$
, $\gamma = 1, \dots, p-s$.

Then since (4.19) is orthogonal

$$\sum_{\alpha} (y_{\alpha} - \mu_{\alpha})^{2} = \sum_{\alpha} (y_{\alpha}^{*} - \mu_{\alpha}^{*})^{2}.$$

, ..., p-s.

Orthogonal $\sum_{\alpha} (y_{\alpha} - \mu_{\alpha})^2 = \sum_{\alpha} (y_{\alpha}^* - \mu_{\alpha}^*)^2.$ 2 the $(y_{\alpha}^* - \mu_{\alpha}^*)$ are norm.

1 mean 0 and ... By Lemma 2.2 the $(y_{\alpha}^* - \mu_{\alpha}^*)$ are normally and independently distributed with mean 0 and variance σ^2 . The assumptions then state that $\mu_{\alpha}^{*}=0$ for α www.debraylikeary per Hence

$$Q_a = \sum_{r=1}^{N-p} y_a^{*2}.$$

Similarly

$$Q_r = \sum_{\alpha=1}^{N-p+s} y_{\alpha}^{*2}$$

and

Similarly
$$Q_r = \sum_{\alpha=1}^{N-p+s} y_{\alpha}^{*2}$$
 and
$$Q_r - Q_a = \sum_{\alpha=N-p+1}^{N-p+s} y_{\alpha}^{*2}.$$

Hence under the assumptions Q_a is a sum of N - p independent squares and Q_a/σ^2 has the χ^2 distribution with N-pdegrees of freedom. Similarly $(Q_r - Q_a)/\sigma^2$ has the χ^2 distribution with s degrees of freedom and $Q_r - Q_a$ and Q_a are independent of each other. Hence

$$(4.24) F = \frac{N-p}{s} \frac{Q_r - Q_s}{Q_s}$$

has the F distribution with s and N - p degrees of freedom respectively. We, therefore, have

Theorem 4.1: Let y_1, \dots, y_N be normally and independently distributed variables with the same variance and means μ_1 , \cdots , μ_N respectively. Assume that the μ_n satisfy the independent relations

$$(4.25) \sum_{\alpha} \lambda_{i\alpha} \mu_{\alpha} = 0 i = 1, \cdots, N-p.$$

To test the hypothesis that the μ_a satisfy relations

To test the hypothesis that the
$$\mu_{\alpha}$$
 satisfy relations
$$(4.26) \qquad \sum_{\alpha} \rho_{i\alpha}\mu_{\alpha} = 0 \quad i = 1, \dots, s \quad s \leq p.$$
independent of the relations (4.25) and of each other we form the

independent of the relations (4.25) and of each other, we form the ratio

(4.27)
$$F = \frac{N - p}{s} \frac{Q_r - Q_a}{Q_a},$$

where Q. is the million with respect to μ_a of $\sum_a (y_a - \mu_a)^2$ under the restrictions (4.25) and Q, the minimum of $\sum_a (y_a - \mu_a)^2$ under the restrictions (4.25) and (4.26). We reject the hypothesis (4.26) if $F \geq F_0$ where $P(F \geq F_0 \mid 4.25 \& 4.26) = \alpha \text{ and } \alpha \text{ is}$ a fixed constant. Then

- 1) The test described is equivalent to the likelihood ratio test for the hypothesis (4.26).
- 2) The ratio (4.27) has the F distribution with s and N-pdegrees of freedom respectively.

We can formulate our assumptions also in the following manner. We have

$$y_{\alpha} = \mu_{\alpha} + \epsilon_{\alpha}$$
,

where the ϵ_{α} are normally and independently distributed variables. According to our assumptions (4.6) we have

$$(4.28) y_{\alpha} = g_{1\alpha}\beta_1 + \cdots + g_{p\alpha}\beta_p + \epsilon_{\alpha}, \alpha = 1, \cdots, N.$$

The equation (4.28) is called a linear regression equation of y on g_1 , \cdots , g_p . The coefficients β_1 , \cdots , β_p are termed the regression coefficients of y on g_1 , \cdots , g_p . We have shown that their maximum likelihood estimates b_1 , \cdots , b_r minimize the expression

$$(4.29) \qquad \sum_{\alpha} (y_{\alpha} - \beta_1 g_{1\alpha} - \cdots - \beta_r g_{r\alpha})^2.$$

Hence we must have

$$\sum_{\alpha} (y_{\alpha} - b_1 g_{1\alpha} - \cdots - b_p g_{\nu\alpha}) g_{i\alpha} = 0,$$

(4.30)

$$i=1,\cdots,p$$

Multiplying the *i*th of the equations (4.30) by b_i , adding over all equations (4.30), and putting

$$(4.31) Y_{\alpha} = b_1 g_{1\alpha} + \cdots + b_p g_{p\alpha}$$

we obtain

$$(4.32) \qquad \sum_{\alpha} (y_{\alpha} - Y_{\alpha}) Y_{\alpha} = 0$$

 $+ b_p g_{p\alpha}$ $\sum_{\alpha} (y_{\alpha} - Y_{\alpha}) Y_{\alpha} = 0.$ is called thear $b^{2\alpha}$ The quantity Y_{α} is called the autimession value of y_{α} on the variables $g_{1\alpha}$, \cdots , $g_{p\alpha}$.

The minimum Q_a under the assumptions is then given by

$$\sum_{\alpha} (y_{\alpha} - Y_{\alpha})^{2} = \sum_{\alpha} (y_{\alpha} - Y_{\alpha})y_{\alpha} - \sum_{\alpha} (y_{\alpha} - Y_{\alpha})Y_{\alpha}$$
(4.33)

$$= \sum_{\alpha} y_{\alpha}^2 - \sum_{\alpha} Y_{\alpha}^2 .$$

Let now Y^* be the regression value of y_{α} on $g_{1\alpha}$, \cdots , $g_{\nu\alpha}$ under the restrictions 4.6 and 4.7. Then similarly

$$Q_{r} = \sum_{\alpha} y_{\alpha}^{2} - \sum_{\alpha} Y_{\alpha}^{*2}.$$

$$(4.35) Q_r - Q_a = \sum_{\alpha} (Y_{\alpha}^2 - Y_{\alpha}^{*2}).$$

The restrictions (4.7) are equivalent to stating that β_1 , \cdots , β_{ν} may be expressed by p-s parameters $\gamma_1, \dots, \gamma_{\nu-s}$.

$$\beta_{i} = \sum_{i} k_{ii} \gamma_{i} . \qquad i = 1, \cdots, p.$$

Let c_1 , \cdots , c_{p-s} be the maximum likelihood estimates of γ_i . Then

$$(4.37) Y_{\alpha}^* = \sum_{i} c_i \sum_{i} g_{i\alpha} k_{ii} .$$

Multiplying the tth of the equations (4.30) by $k_{\rm OCO}$ and summing over t and l we obtain

(4.38)
$$\sum_{\alpha} (y_{\alpha} - Y_{\alpha}) Y_{\alpha}^{*} = 0.$$

Since also $\sum_{\alpha} (y_{\alpha} - Y_{\alpha}^*) Y_{\alpha}^* = 0$ we obtain

$$\sum_{\alpha} (Y_{\alpha} - Y_{\alpha}^{*}) Y_{\alpha}^{*} = \sum_{\alpha} (y_{\alpha} - Y_{\alpha}^{*}) Y_{\alpha}^{*}$$

$$(y_{\alpha} - Y_{\alpha}^{*})Y_{\alpha}^{*}$$

$$- \sum_{\alpha} (y_{\alpha} - Y_{\alpha})Y_{\alpha}^{*} = \theta.$$

$$\sum_{\alpha} (Y_{\alpha} - Y_{\alpha}^{*})Y_{\alpha}$$

$$V.org.in$$

Hence

$$\sum_{\alpha} (Y_{\alpha} - Y_{\alpha}^*)^2 = \sum_{\alpha} (Y_{\alpha} - Y_{\alpha}^*) Y_{\alpha}$$

(4.39)
$$= \sum_{\alpha} Y_{\alpha}^{*} - \sum_{\alpha} Y_{\alpha}^{*2}.$$

Therefore

(4.40)
$$Q_r - Q_a = \sum_{\alpha} (Y_{\alpha} - Y_{\alpha}^*)$$

and

Hence
$$\sum_{\alpha} (Y_{\alpha} - Y_{\alpha}^{*})^{2} = \sum_{\alpha} (Y_{\alpha} - Y_{\alpha}^{*}) Y_{\alpha}$$

$$= \sum_{\alpha} (Y_{\alpha} - Y_{\alpha}^{*})^{2} - \sum_{\alpha} (Y_{\alpha}^{*} - Y_{\alpha}^{*}) Y_{\alpha}$$

$$= \sum_{\alpha} (Y_{\alpha}^{2} - Y_{\alpha}^{*})^{2} - \sum_{\alpha} (Y_{\alpha}^{*} - Y_{\alpha}^{*})^{2}$$

$$= \frac{(N - p)}{s} \frac{\sum_{\alpha} (Y_{\alpha} - Y_{\alpha}^{*})^{2}}{\sum_{\alpha} (y_{\alpha} - Y_{\alpha})^{2}}$$

$$= \frac{N - p}{s} \frac{\sum_{\alpha} (Y_{\alpha}^{2} - \sum_{\alpha} (Y_{\alpha}^{*} - Y_{\alpha}^{*})^{2}}{\sum_{\alpha} (Y_{\alpha}^{2} - \sum_{\alpha} (Y_{\alpha}^{*} - Y_{\alpha}^{*})^{2}}.$$

$$= \frac{N - p}{s} \frac{\sum_{\alpha} (Y_{\alpha}^{2} - \sum_{\alpha} (Y_{\alpha}^{*} - Y_{\alpha}^{*})^{2}}{\sum_{\alpha} (Y_{\alpha}^{2} - \sum_{\alpha} (Y_{\alpha}^{*} - Y_{\alpha}^{*})^{2}}.$$

Testing a linear hypothesis means essentially testing the significance of the coefficients of a regression equation.

From (4.33) and (4.39) it follows also that

$$(4.42) \qquad \sum_{\alpha} (y_{\alpha} - Y_{\alpha})^{2} = \sum_{\alpha} y_{\alpha}^{2} - \sum_{\alpha} Y_{\alpha}^{*2} - \sum_{\alpha} (Y_{\alpha} - Y_{\alpha}^{*})^{2}.$$

This result can easily be generalized to yield

THEOREM 4.2: Let H_1 , \cdots , H_s be a sequence of hypotheses on the means of the variables y_a with $E(y_a) = \mu_a$ of the form

$$H_1: \qquad \mu_\alpha = \sum_{i=1}^p g_{i\alpha}\beta_i \; ,$$

$$H_i: H_1 \& H_2 \cdots \& H_{i-1} \& \sum_i a_{ki}\beta_i = 0,$$

$$k = s_{t-1} + 1, \cdots, s_t, \quad s_t \leq p$$

such that the linear restrictions imposed by H, are independent of each other. Let $Y_{\alpha}^{(i)}$ be the regression value of y_{α} obtained under the hypothesis H, then

the hypothesis
$$H_{\star}$$
 then
$$\sum_{\alpha} y_{\alpha}^{2} = \sum_{\alpha} (y_{\alpha} - Y_{\alpha}^{(1)})^{2} + \sum_{\alpha} (Y_{\alpha}^{(1)} - Y_{\alpha}^{(2)})^{2} + \cdots + \sum_{\alpha} (Y_{\alpha}^{(4)} - Y_{\alpha}^{(2)})^{2} + \sum_{\alpha} (Y_{\alpha}^{(4)})^{2}.$$

Theorem 4.2 is very useful in reducing the labor involved in computing sums of squares of deviations from a regression value.

We now turn our attention to the solution of the equation (4.30). We write

$$(4.44) \qquad \sum_{\alpha} g_{i\alpha}g_{i\alpha} = a_{ii} , \qquad \sum_{\alpha} y_{\alpha}g_{i\alpha} = a_{i} .$$

Lemma 4.2: Let $g = (g_{i,\alpha})$, $(i = 1, \dots, p, \alpha = 1, \dots, N)$, be any matrix of rank $p \leq N$. Put $gg' = (a_{ij})$. Then the quadratic form $\sum_{i} \sum_{j} a_{ij}x_{i}x_{j}$ is positive definite.

Proof: Consider

$$\sum_{\alpha} \left(\sum_{i=1}^{i=p} g_{i\alpha} x_i \right)^2 = \sum_{\alpha} \sum_{i} \sum_{i} g_{i\alpha} g_{i\alpha} x_i x_i$$
$$= \sum_{i} \sum_{i} a_{ii} x_i x_i = Q.$$

clearly Q is either positive definite or positive semi definite. If Q = 0 then

$$(4.45) \sum_{i} g_{i\alpha}x_{i} = 0, \alpha = 1, \cdots, N.$$

Since g has the rank p there are p linearly independent equations in (4.45). Therefore, (4.45) has only the solution $x_i = 0$, $i = 1, \dots, p$. Hence Q is positive definite.

Corollary to lemma 4.2. The determinant | aii | is different from 0.

This follows from the fact that all the principal minors of a

$$(4.46) \sum_{i} a_{ii}b_{i} = a_{i}, \quad i = 1, \dots, p,$$

This follows from the fact that all the principal minors of positive definite matrix are positive.

We may rewrite (4.30) as

$$(4.46) \qquad \sum_{i} a_{ii}b_{i} = a_{i} , \quad i = 1, \cdots, p,$$
or in matrix form

$$(4.47) \qquad (a_{ii})(b) = (a), \qquad b = \begin{bmatrix} b_{1} \\ \vdots \\ b_{p} \end{bmatrix}, \qquad (a) = \begin{bmatrix} a_{1} \\ \vdots \\ a_{p} \end{bmatrix}$$
Since by the corollary to lemma 4.2 (a_{ij}) is non singular have with $(a^{ij}) = (a_{ij})^{-1}$

Since by the corollary to lemma 4.2 (a_{ij}) is non singular we have with $(a^{ij}) = (a_{ij})^{-1}$

$$(4.48) b = (a^{ij})(a)$$

(4.48)
$$b = (a^{ij})(a)$$
 or
$$(4.48') b_i = \sum_i a^{ij} a_i , i = 1, \dots, p.$$
 We see that b_i is a linear function with constant the i^{ij} . Hence if the a^{ij} are initial.

We see that b, is a linear function with constant coefficients of the y_a . Hence if the y_a are jointly normally distributed, then the b, are jointly normally distributed and their distribution is completely specified if we know their means and their covariance matrix. We have putting

$$\delta_{ii} = \begin{cases} 0 & \text{for } i \neq j \\ 1 & \text{for } i = j, \end{cases}$$

$$(4.49) E(b_i) = \sum_i a^{ii} \sum_{\alpha} g_{i\alpha} E(y_{\alpha}) = \sum_i a^{ii} \sum_{\alpha} \sum_{l} g_{i\alpha} g_{l\alpha} \beta_{l}$$

$$= \sum_i \sum_i a^{ii} a_{il} \beta_{l} = \sum_i \delta_{il} \beta_{l} = \beta_i.$$

Thus b_i is an unbiased estimate of β_i . Further

$$\sigma_{b_ib_j} = \sum_k \sum_l a^{ik} a^{il} \sigma_{a_k a_l} = \sum_k \sum_l a^{ik} a^{il} \sum_{\alpha} \sum_{\beta} g_{k\alpha} g_{l\beta} \sigma_{v\alpha v\beta}.$$

But
$$\sigma_{y_{\alpha}y_{\beta}} = 0$$
 if $\alpha \neq \beta$ and $\sigma_{y_{\alpha}}^2 = \sigma^2$. Hence
$$\dot{\sigma}_{b_ib_i} = \sigma^2 \sum_k \sum_l a^{ik} a^{il} \sum_{\alpha} g_{k\alpha} g_{l\alpha} = \sigma^2 \sum_k \sum_l a^{ik} a^{il} d_{kl}$$
(4.50)

(4.50)
$$= \sigma^2 \sum_{k} a^{ik} \delta_{ik} = a^{ij} \sigma^2.$$

We proceed to prove

www.dbraulibrary.org.in THEOREM 4.3: Let Qa be the minimum of the quadratic form $\sum_{\alpha} (y_{\alpha} - E(y_{\alpha}))^2$ under the assumption

$$(4.51) E(y_{\alpha}) = \sum_{i=1}^{s} \beta_{i} g_{i\alpha} + \sum_{d=s+1}^{p} \beta_{d} g_{d\alpha}, \alpha = 1, \cdots, N.$$

and Q, its minimum under the restrictions $\beta_i = 0$, $i = 1, \dots$, s. Let b_i , $(i = 1, \dots, s)$, $b_d(d = s + 1, \dots, p)$ be the least square estimates of β_1 , β_2 , \cdots , β_r under the restrictions (4.51) and put

$$\left(\frac{\sigma_{b_ib_i}}{\sigma^2}\right)^{-1} = (c_{ij}).$$

$$(4.52) Q_r - Q_a = \sum_i \sum_j c_{ij} b_i b_i .$$

In the following let i, j, k run from 1 to s; d, e, f from s + 1to p; σ , τ from 1 to p.

Put

$$\begin{pmatrix}
a_{ii} & a_{id} \\
a_{di} & a_{ds}
\end{pmatrix}^{-1} = \begin{pmatrix}
a^{ii} & a^{id} \\
a^{di} & a^{ds}
\end{pmatrix}, \qquad (a_{ds})^{-1} = (a^{rds}).$$

Then by (4.50)

$$(4.54) (a^{ii})^{-1} = (c_{ii}).$$

We have

$$Q_{\alpha} = \sum_{\alpha} y_{\alpha}^{2} - \sum_{\alpha} Y_{\alpha}^{2} = \sum_{\alpha} y_{\alpha}^{2} - \sum_{\alpha} \sum_{\sigma} \sum_{\tau} g_{\sigma\alpha}g_{\tau\alpha}b_{\sigma}b_{\tau}$$

$$= \sum_{\alpha} y_{\alpha}^{2} - \sum_{\sigma} \sum_{\alpha} a_{\sigma\tau}b_{\sigma}b_{\tau} = \sum_{\alpha} y_{\alpha}^{2} - \sum_{\sigma} a_{\sigma}b_{\sigma}.$$

$$(4.55)$$

Let b_d^* , d=s+1, $\cdots p$ be the regression values for β_d obtained under the hypothesis $\beta_1 = \cdots \beta_n = 0$. Then by (4.55)

$$Q_r - Q_a = \sum_i a_i b_i + \sum_d a_d b_d - \sum_d a_d b_d^*$$

www.dbr $\sum_i i b_i d_{ar} + cr \sum_d i a_d (b_d - b_d^*)$.

But from (4.46) we have

$$\sum_{s=s+1}^{p} a_{ds}(b_{s} - b_{s}^{*}) = -\sum_{i} a_{di}b_{i} .$$

Hence

(4.56)

$$(4.57) b_i - b_i^* = -\sum_{d} a^{ids} \sum_{i} a_{di} b_i ,$$

and from (4.46), (4.56) and (4.57)

$$Q_{r} - Q_{a} = \sum_{i} b_{i} \left(\sum_{j} a_{ij} b_{j} + \sum_{d} a_{id} b_{d} \right)$$

$$- \sum_{d} a_{d} \sum_{e} a^{rde} \sum_{j} a_{ej} b_{j}$$

$$= \sum_{i} b_{i} \left(\sum_{j} a_{ij} b_{j} + \sum_{d} a_{id} b_{d} \right)$$

$$- \sum_{d} \sum_{e} \sum_{k} \sum_{j} a_{dk} a^{rde} a_{ej} b_{j} b_{k}$$

$$- \sum_{i} \sum_{k} \sum_{j} a_{dr} a^{rde} a_{ej} b_{j} b_{f}.$$

The coefficient of $b_i b_i$ in the expression (4.58) is given by

$$a_{if} - \sum_{d} \sum_{\bullet} a_{di} a'^{d\bullet} a_{\bullet i} = a_{if} - \sum_{\bullet} \delta_{\bullet f} a_{\bullet i}$$

(4.59)

$$=a_{ij}-a_{fi}=0.$$

The coefficient of $b_i b_k$ is given by

$$(4.60) a_{ik} - \sum_{d} \sum_{e} a_{dk} a'^{de} a_{ei} = \bar{c}_{ik}.$$

Our theorem is proved if we can prove that $\bar{c}_{ik}=c_{jk}$. This is proved if we can show that $\sum_i a^{ij} \bar{c}_{ik}=\delta_{ik}$. We have

$$(4.61) \qquad \sum_{i} a^{ij} \ddot{c}_{ik} = \sum_{i} a^{ij} a_{ik} - \sum_{i} \sum_{d} \sum_{e} a^{ij} a_{dk} a^{ide} a_{ei} .$$

Now

$$\sum_i a^{ii} a_{*i} \overset{\text{def}}{\sim} \overset{\sum_j dh_i \overset{\text{def}}{\sim} dh_i \overset{\text{def}}{\sim} \Sigma_i \overset{\text{def}}{\sim} 0.$$

Hence (4.61) becomes

1) becomes
$$\sum_{i} a^{ij} a_{ik} + \sum_{d} \sum_{e} \sum_{f} a^{if} a_{ef} a^{fde} a_{dk}$$

$$= \sum_{i} a^{if} a_{ik} + \sum_{d} \sum_{f} a^{if} \delta_{fd} a_{dk}$$

$$= \sum_{i} a^{ij} a_{ik} + \sum_{d} a^{id} a_{dk} = \delta_{ik}.$$

Hence $\bar{c}_{ij} = c_{ij}$ and theorem 4.3 is proved.

Corollary 1 of theorem 4.3. Let the hypothesis in theorem 4.3 be

$$(4.62) \beta_i^* = \sum_{i=1}^p l_{ii}\beta_i = 0, i = 1, \cdots, s \leq p,$$

where the rank of (l_{ii}) is s. Put

$$\sum_{i} l_{ii}b_{i} = b_{i}^{*} \quad and \quad \left(\frac{\sigma_{b_{i}*b_{j}*}}{\sigma^{2}}\right)^{-1} = c_{ij}.$$

Then

$$(4.63) Q_r - Q_a = \sum_i \sum_i c_{ii} b_i^* b_i^*.$$

Proof: Since the rank of (l_{ii}) is s we can add p-s rows to (l_{ii}) to obtain a non singular matrix (l_{iv}) with p rows and p columns. The β_i are then also linear functions of $\beta_r^* = \sum_i l_{vi}\beta_i$, $v = 1, \dots, p$. Clearly $b_r^* = \sum_i l_{vi}b_i$ must minimize Q_a and the corollary follows by applying theorem 4.3.

The most important special case of theorem 4.3 and its corollary is the case where s=1 then

$$Q_r - Q_a = \frac{b_1^2 \sigma^2}{\sigma_{b_1}^2}.$$

In finding Q_a it is sometimes required to minimize $Q = \sum_{\alpha} (y_{\alpha} - \sum_{i} g_{\alpha i} \beta_{i})^{2}$ under some linear restrictions on the β_{i}

(4.65)
$$\sum_{i=1}^{p} l_{ii}\beta_{i} = L_{i} = 0, \quad i = 1, \dots, s,$$
www.dbraulibrary.org.in
$$\operatorname{rank}(l_{ii}) = s < p.$$

Then s of the β_i can be expressed as functions of p-s of them and the regression problem may thus be reduced to a regression problem in p-s of the β_i .

Suppose that all the β 's can, by means of (4.65), be presented as linear functions of β_1^* , \cdots , β_t^* , β_{t+1}^* , \cdots , β_{r-s}^* , where the β_i^* are linear functions of β_1 , \cdots , β_r and that we test the hypothesis $\beta_i^* = \cdots = \beta_i^* = 0$. Then theorem 4.3 also applies to the maximum likelihood estimates b_1^* , \cdots , b_i^* , since we can write Q as a function of β_1^* , \cdots , β_{r-s}^* .

Instead of the elimination procedure of the preceding paragraph, it is often more convenient to employ the method of Lagrange operators. This method consists in differentiating the expression

$$(4.66) Q + \lambda_1 L_1 + \cdots + \lambda_s L_s = Q',$$

with respect to β_1 , \cdots , β_{ν} and solving (4.65) together with

(4.67)
$$\frac{\partial Q'}{\partial \beta_i} = 0, \quad i = 1, \dots, p$$

for the s + p unknown quantities β_1, \dots, β_p and $\lambda_1, \dots, \beta_p$ λ_s . The values for β_1 , \cdots , β_s obtained in this way are exactly the maximum likelihood estimates b_1 , \cdots , b_p obtained under the restrictions (4.65). A full account of Lagrange's method is given in Hancock "Theory of Maxima and Minima Chapter VI".

The regression coefficient β_p in (4.6) will be termed the general mean if $g_{\nu\alpha} = 1$ for all α .

Theorem 4.4: Let

$$E(y_{\alpha}) = \mu_{\alpha} = \sum_{i=1}^{p} g_{i\alpha}\beta_{i} .$$

 $Assume\ that$

1) β_p is the general mean. www.dbraulibrary.org.in

2)
$$g_{i\alpha}$$
 is either 0 or 1, $i = 1, \dots, s$.

3)
$$\sum_{\alpha} g_{i\alpha}g_{i\alpha} = 0$$
 if $i \neq j, i, j \leq s$

2)
$$g_{i\alpha}$$
 is either 0 or 1, $i = 1, \dots, s$.
3) $\sum_{\alpha} g_{i\alpha}g_{i\alpha} = 0$ if $i \neq j, i, j \leq s$.
4) $\sum_{i=1}^{s} g_{i\alpha}^{2} = 1$ $\alpha = 1, \dots, N$.
If
$$Q = \sum_{i=1}^{s} \left(y_{\alpha} - \sum_{i=1}^{p} g_{i\alpha}\beta_{i}\right)^{2}$$

$$Q = \sum \left(y_{\alpha} - \sum_{i=1}^{p} g_{i\alpha} \beta_{i} \right)^{2}$$

is minimized with respect to

$$eta_1, \dots, eta_p$$
 and $\sum_{i=1}^s t_i eta_i = 0, \sum t_i \neq 0$

is the only restriction on β_1 , \cdots , β_s , β_p and if λ_1 is the Lagrange multiplier associated with

$$\sum_{i=1}^{3} t_i \beta_i \quad then \quad \lambda_1 = 0.$$

It may be emphasized that any number of restrictions may be imposed on β_{s+1} , \cdots , β_{s-1} . Denoting by b_1 , \cdots , b_s the least square estimates of β_1 , \cdots , β_{ν} we obtain the following equations

$$\sum_{\alpha} y_{\alpha} g_{i\alpha} - b_{i} \sum_{\alpha} g_{i\alpha}^{2} - \sum_{d=s+1}^{p} b_{d} \sum_{\alpha} g_{d\alpha} g_{i\alpha} - \frac{t_{i} \lambda_{1}}{2} = 0,$$

(4.68)

$$=1,\cdots,s$$

$$\sum_{\alpha} y_{\alpha} - \sum_{i=1}^{s} b_{i} \sum_{\alpha} g_{i\alpha} - \sum_{d=s+1}^{p} b_{d} \sum_{\alpha} g_{d\alpha} = 0.$$

Because of the conditions 1, 2, 3, 4 we have
$$\sum_{\alpha} y_{\alpha} = \sum_{\alpha} \sum_{i=1}^{s} y_{\alpha} g_{i\alpha} , \qquad \sum_{\alpha} g_{i\alpha} = \sum_{\alpha} g_{i\alpha}^{2} ,$$
(4.69)

www.diraglibrary.org.)
$$\sum_{i=1}^{n} \sum_{\alpha}^{g_{i\alpha}g_{d\alpha}} g_{i\alpha}g_{d\alpha} = \sum_{\alpha}^{n} g_{d\alpha}$$
.

If we sum the first of the relations (4.68) from $i=1, \dots, s$ we obtain $\lambda_1 = 0$ on account of the relations (4.69).

THEOREM 4.5: Let

$$Q = \sum_{\alpha} (y_{\alpha} - \sum_{i} g_{i\alpha} \beta_{i})^{2}.$$

Let Q. be the minimum of Q under the restrictions

$$\sum_{i=1}^s \beta_i = 0$$

and other restrictions involving eta_{z+1} , \cdots , eta_{z} only. Let b_1 , \cdots , b, be the least square estimates of eta_1 , \cdots eta_s under these restrictions. Let Q, be the minimum under the restrictions $\beta_1 = \cdots = \beta_r = 0$ and all other restrictions.

If $Q_r - Q_a$ is a symmetric function of b_1 , \cdots , b_a and if the assumptions of theorem 4.4 are satisfied then

(4.70)
$$Q_r - Q_o = \frac{s-1}{sc} \sum_{i=1}^s b_i^2, \qquad \sigma_{b_i}^2 = c\sigma^2.$$

Proof: $Q_r = Q_a$ is by theorem 4.3 a quadratic form in b_1 , \cdots , b_a . Since it is symmetric in b_1 , \cdots , b_a and since

$$\sum_{i=1}^s b_i = 0$$

we must have

$$(4.71) \quad Q_r - Q_a = h \sum_{i=1}^{s} b_i^2 + k \sum_{i,j=1}^{s} b_i b_j = K \sum_{i=1}^{s} b_i^2$$

Because of the symmetry, the variances of the b_i must all be equal to each other. $Q_r - Q_a$ has by theorem 4.1 the χ^2 distribution with (s-1) degrees of freedom. Hence

(4.72)
$$E(Q_r - Q_\sigma) = (s - 1)\sigma^2 = Ksc\sigma^2$$

and theorem 4.5 follows.

We now proceed to present some bapplications of the principles developed in this chapter.

Example 1. Consider a regression equation

$$(4.74) E(y) = \beta_1 + \beta_2 x,$$

where the values of y have been observed for certain values of x. For instance y may be the length of a steel rod and x the temperature at which this length is measured. We have then a set of observations

$$y_1$$
, \cdots , y_N

of the variable y observed when the variable x had the values x_1 , \cdots , x_N . We might wish to test whether β_2 has some hypothetical value $\overline{\beta}_2$. We then rewrite (4.74) as

(4.75)
$$E(y - \overline{\beta}_2 x) = \beta_1 + (\beta_2 - \overline{\beta}_2)x.$$

Treating now $y_{\alpha} - \bar{\beta}_2 x_{\alpha} = y'_{\alpha}$ as the independent variable we may apply Theorem 4.3 to the regression coefficient $\beta_2 - \bar{\beta}_2 = \beta_2^*$. If Y'_{α} is the regression value of y'_{α} on β_1 and β_2^* and b_2^* the least square estimate of β_2^* and $c\sigma^2$ its variance then we use

(4.76)
$$F = \frac{N-2}{1} \frac{b_2^{*2}}{c(\sum y'_{\alpha} - \sum Y'_{\alpha})}$$

as a statistic to test the hypothesis $\beta_2^* = 0$. By Theorem 4.1 F has the F distribution with 1 and N-2 degrees of freedom respectively.

From (4.76) we can see the intuitive reason for using the test function F. The total observed sum of squares of deviations

$$\sum_{\alpha} (y_{\alpha} - \overline{y})^{2} \quad \text{where} \quad \overline{y} = \frac{y_{1} + \dots + y_{N}}{N}$$

has been divided into two components;

has been divided into two components;
$$\sum_{\alpha} (y_{\alpha} - Y_{\alpha})^{2} \quad \text{and} \quad \sum_{\alpha} (Y_{\alpha} - \overline{y})^{2} = \frac{b_{2}^{*2}}{c} = (Q_{c} - Q_{a}).$$
 Each of the two quadratic forms in y_{α} divided by its rank

Each of the two quadratic forms in y_a divided by its rank (degrees of freedom) gives us an estimate of the variance σ^3 . But whilst the estimate of σ^2 appearing in the denominator of (4.76) is independent of the value of β_2^* , the numerator is an estimate of σ^2 only if $\beta_2^* = 0$. If $\beta_2^* \neq 0$ then the numerator will tend to be larger than σ^2 .

Example 2. Suppose now that y is again the length of a steel bar and x its temperature. We wish to test whether the length of a steel bar is a linear function of the temperature, whilst admitting the alternative possibility that the function be of second degree. Our assumption will then be

(4.77)
$$E(y) = \beta_1 + \beta_2 x + \beta_3 x^2,$$

where the length y of the steel bar is measured at different temperatures x_1 , ..., x_N . In terms of theorems 4.1 and 4.3 we have

$$g_{1\alpha}=1, \qquad g_{2\alpha}=x_{\alpha}, \qquad g_{3\alpha}=x_{\alpha}^2.$$

The hypothesis to be tested is $\beta_3 = 0$. The first step is then to estimate β_1 , β_2 , β_3 by least squares. Then if $\sigma_{b_1}^2 = c\sigma^2$, where c can be computed from the $g_{i\alpha}$, and b_3 is the least square estimate of \$3.

$$F = \frac{N-3}{1} \frac{b_3^2}{Q_a}$$

has the F distribution with 1 and N-3 degrees of freedom respectively.

Example 3. We shall consider again the one way classification problem treated in Chapter 3. We assumed that we had taken a sample of n_1x 's from the first classification, n_2 from the second and so on. Denoting by x_{ij} the jth measurement in the ith class we have to consider the following linear hypothesis.

Assumption

$$E(x_{ij}) = \mu_i$$
 for $i = 1, \dots, s, \quad j = 1, \dots, n_i$.

The hypothesis to be tested is $\mu_1 = \cdots = \mu_s$. The number of independent linear constraints imposed by the assumption is $n_1 + n_2 + \cdots + n_s - s = n - s$. The number of linear constraints imposed by the hypothesis is s - 1. To obtain Q_a we have to minimize www.dbraultbrary.org.in

(4.78)
$$\sum_{i=1}^{s} \sum_{j=1}^{n_i} (x_{ij} - \mu_i)^2.$$

Let m_i be the least square estimates of μ_i . Then

(4.79)
$$m_i = \frac{1}{n_i} \sum_i x_{i,i} = x_i$$
, $i = 1, \dots, s$.

Hence if Y_{ij} is the regression value of x_{ij} on μ_1 , \cdots , μ_s we have

$$(4.80) Y_{ij} = x_{i\cdot}, (i = 1, \dots, s, j = 1, \dots, n_i).$$

To obtain Q_r , we have to minimize $\sum_i \sum_i (x_{ii} - \mu)^2$ which yields as regression value the mean x of all observations. It follows then from Theorem 4.1 and equation 4.1 that

(4.81)
$$F = \frac{n-s}{s-1} \frac{\sum_{i} n_{i} x_{i}^{2} - n x^{2}}{\sum_{i} \sum_{i} (x_{i})^{2} - \sum_{i} n_{i} x_{i}^{2}}.$$

is the likelihood ratio statistic for testing our hypothesis.

Example 4. We shall now treat the problem of a 2 way classification. As an example suppose that $r \cdot s$ pigs from r different races receive s different diets such that exactly one

the *i*th race $(i = 1, \dots, r)$ receives the *j*th dies j = 1, ..., s. The purpose of the experiment is two fold. We want to see if the pig races differ with respect to the weight gains and at the same time we should like to know if the different diets differ in their ability to produce weight gains.

Our observations can be arranged into a matrix

$$\begin{pmatrix}
 x_{11}, \dots, x_{1s} \\
 \vdots \\
 \vdots \\
 x_{r1}, \dots, x_{rs}
 \end{pmatrix},$$

Hary.org.i where xii is the weight gain of the pig from the ith race which receives the ith diet.

We assume now that the weight gain is produced by two factors, race and deedy both you which act independently of each other. Moreover we shall assume that the x_{ij} are normally and independently distributed all with the same variance.

Our linear hypothesis is then the following

(4.82)
$$E(x_{ij}) = \mu_i + \mu_{ij} + \mu_j \qquad \sum \mu_{ij} = \sum \mu_{ij} = 0,$$

where μ_i is the "effect" of the *i*th race μ_i , the "effect" of the jth diet, and μ is a constant independent of i and j.

To find Q_{α} we have to minimize $\sum_{i} \sum_{i} (x_{ij} - \mu_{i} - \mu_{ij} - \mu)^{2}$ subject to the restriction of (4.82). The conditions of theorem 4.4 are however obviously satisfied and we may therefore ignore the restrictions. Thus if m_i , m_{ij} , m are the least square estimates of μ_i , μ_{ij} , μ we have

$$m = \frac{1}{rs} \sum_{i} \sum_{i} x_{ii} = x,$$

$$m_{i} = \frac{1}{s} \sum_{i} x_{ii} - m = x_{i.} - x,$$

$$m_{i} = \frac{1}{r} \sum_{i} x_{ii} - m = x_{ii} - x.$$

Thus the regression value Y_{ij} is given by

$$(4.83) Y_{ij} = x_i + x_{ij} - x_i$$

We now apply theorem 4.2 and consider the sequence of hypotheses

$$H_{1}: \quad \mu_{ij} = \mu_{i}. + \mu_{\cdot j} + \mu_{i}$$

$$(4.84) \quad H_{2}: \quad H_{1} \& \mu_{i}. = 0,$$

$$H_{3}: \quad H_{1} \& H_{2} \& \mu_{\cdot j} = 0.$$
It is easily seen that the regression values are
$$Y_{ij}^{(1)} = x_{i}. + x_{\cdot j} - x_{i}$$

$$(4.85) \quad Y_{ij}^{(2)} = x_{\cdot j},$$

It is easily seen that the regression values are

$$Y_{ii}^{(1)} = x_i. + x_{\cdot i} - x,$$

$$Y_{ii}^{(2)} = x_{\cdot i},$$

$$Y_{ii}^{(3)} \overset{\vee}{=} \overset{\vee}{x}.^{\text{dbraulibrary.org.in}}$$

Hence by theorem 4.2

Hence by theorem 4.2
$$Q_a = \sum_{i,j} (x_{ij} - x_i, -x_{ij} + x)^2$$

$$= \sum_{i,j} x_{ij}^2 - s \sum_i (x_i, -x)^2 - r \sum_i (x_{ij} - x)^2 - rsx^2.$$

For testing $H_2: \mu_i = 0$ we have

$$(4.87) \quad Q_r - Q_s = \sum_{i,j} (Y_{ij}^{(1)} - Y_{ij}^{(2)})^2 = s \sum_i (x_i - x)^2.$$

Similarly for testing $H'_2: \mu_{i} = 0$ we obtain

$$(4.88) Q_r - Q_s = r \sum_i (x_{i} - x)^2.$$

We can further simplify (4.86), (4.87), (4.88) by means of (3.1) and applying theorem 4.1 we find that

(4.89)
$$F_{2} = \frac{(r-1)(s-1)}{r-1} \cdot \frac{s \sum x_{i}^{2} - rsx^{2}}{\sum_{i,j} x_{ij}^{2} - s \sum x_{i}^{2} - r \sum x_{i,j}^{2} + rsx^{2}}$$

and

$$F_2' = \frac{(r-1)(s-1)}{s-1}$$

(4.90)

$$\frac{r \sum x_{i}^{2} - rsx^{2}}{\sum_{i} \sum_{i} x_{ii}^{2} - s \sum x_{i}^{2} - r \sum x_{i}^{2} + rsx^{2}}$$

and an otheses H_2 :

CHAPTER V

Analysis of Variance in an r-way Classification Design

Let us again consider example 4 of chapter 4. We had rs quantities x_{ii} ($i=1, \dots, r; j=1, \dots, s$). The observations could be arranged in classes in two ways and x_{ij} was the value observed in the *i*th class of the first and in the *j*th class of the second classification.

This idea can be generalized and we shall in this chapter consider r-way classification designs and their analysis for any r. For practical reasons r will be limited to at most 4 or 5; however, a general treatment of r-way classification designs is just as easy as the treatment of special cases and we shall give it here in all generality.

To give an example of a 3-way classification suppose that we have 10 weather stations. The mean rainfall was recorded by these 10 stations every month in 5 successive years. Every observation is then characterized by 3 numbers, the number of the weather station, the month, and the year in which the observation was made. Thus the observations may be denoted by $x_{a_1a_2a_3}$ ($a_1=1,\cdots,10; a_2=1,\cdots,12; a_3=1,\cdots,5$), where a_1 is the number of the weather station, a_2 the month, and a_3 the year of observation.

We may for instance want to know whether rainfall was different in different locations or in different years. Differences between different months are certain to be present.

These simple questions do not however exhaust the information in which we might be interested. It is of interest to know also whether the combination of a certain location with a certain month has any bearing on the amount of rainfall, or whether rainfall was unusually large in July of a particular year. Accordingly we conceive the mean rainfall in one particular station during one particular month and in one particular year as being made up of the effects of station, month and year as well as of the effect of the interaction of month and year, month and station,

year and station and finally one effect due to the interaction of month, year and station. Thus

$$E(x_{a_1a_2a_3}) = \mu(1, 2, 3; a_1, a_2, a_3) + \mu(1, 2; a_1, a_2) + \mu(2, 3; a_2, a_3) + \mu(1, 3; a_1, a_3) + \mu(1; a_1) + \mu(2; a_2) + \mu(3; a_3) + \mu,$$

where

$$\begin{split} \sum_{a_i} \mu(1, 2, 3; a_1, a_2, a_3) \\ &= \sum_{a_2} \mu(1, 2, 3; a_1, a_2, a_3) = \sum_{a_1} \mu(1, 2, 3; a_1, a_2, a_3) \\ &= \sum_{a_{i_1}} \mu(i_1, i_2; a_{i_1}, a_{i_2}) = \sum_{a_{i_2}} \mu(i_1, i_2; a_{i_1}, a_{i_2}) \\ &= \sum_{a_{i_1}} \mu(i_1; a_{i_1}) = 0. \end{split}$$

For instance $\mu(1, 2; 3, 5)$ denotes the effect of the coincidence of station number 3 with month number 5. The assumption can also be written as

$$x_{a_1a_2a_3} = \mu(1, 2, 3; a_1, a_2, a_3) + \mu(1, 2; a_1, a_2) + \mu(2, 3; a_2, a_3) + \mu(1, 3; a_1, a_3) + \mu(1; a_1) + \mu(2; a_2) + \mu(3; a_3) + \mu + \epsilon_{a_1a_2a_3}.$$

We shall assume that the $\epsilon_{a_1a_1a_2}$ are normally and independently distributed all with mean value 0 and the same unknown variance σ^2 .

Generally in an r-way classification we shall assume that

(5.3)
$$E(x_{a_1,\ldots,a_r}) = \sum_{\alpha=0}^{r} \sum_{1,2,\ldots,r} \mu(i_1,\ldots,i_{\alpha};\alpha_{i_1},\ldots,\alpha_{i_{\alpha}}),$$

$$(a_i = 1, \ldots, t_i),$$

$$\sum_{\alpha=1}^{t_{i_1}} \mu(i_1,\ldots,i_k;\alpha_{i_1},\ldots,\alpha_{i_k}) = 0,$$

where the second summation is defined as a constant μ when $\alpha = 0$ and $\sum_{i_1, \dots, r} \mu(i_1, \dots, i_{\alpha}; a_{i_1}, \dots, a_{i_{\alpha}})$ denotes summation over all combinations i_1, \dots, i_{α} chosen from $1, \dots, r$ with $i_1 < i_2 < \dots < i_{\alpha}$. The quantity $\mu(i_1, \dots, i_{\alpha}; a_{i_1}, \dots, a_{i_{\alpha}})$ is called an $(\alpha - 1)$ st order interaction.

We shall denote by $x(i_1, \dots, i_k; a_1, \dots, a_k)$ the mean of all observations in class a_1 of classification i_1 , class a_2 of classification i_2, \dots, i_k of classification i_k and by $\sum_{i_1,\dots,i_k} f(k_1, \dots, k_\alpha)$. The sum of all $f(k_1, \dots, k_\alpha)$ for all choices $k_1 < k_2 < \dots < k_\alpha$ out of $i_1 < i_2 < \dots < i_k$, $\alpha \le k$.

We then consider hypotheses $H_{(i_1, \dots, i_k)}: \mu(i_1, \dots, i_k)$; $a_1, \dots, a_k) = 0$ for all a_1, \dots, a_k . We arrange these hypotheses into a sequence as in Theorem 4.2 in such a way that higher order interactions precede lower order interactions. Interactions of the same order may be arranged in any arbitrary way. In computing Q, we shall hist put the term resulting from the Lagrange multipliers equal to 0. It will then be easy to verify that the least square estimates for the μ 's obtained in this way always satisfy the restrictions 5.3 and that they are moreover unique solutions of the minimum problem. Minimizing

$$Q = \sum_{a_1} \cdots \sum_{a_r} \left[x_{a_1}, \dots, a_r \right]$$
$$- \sum_{\alpha=0}^{r} \sum_{1,\dots,r} \mu(i_1, \dots, i_{\alpha}; a_{i_1}, \dots, a_{i_{\alpha}}) \right]^2$$

under the hypotheses considered and denoting by $A(i_1, \dots, i_{\alpha}; a_1, \dots, a_{\alpha})$ the maximum likelihood estimate of $\mu(i_1, \dots, i_{\alpha}; a_1, \dots, a_{\alpha})$ leads to the equations:

$$(5.4) x(i_1, \dots, i_{\alpha}; a_{i_1}, \dots, a_{i_{\alpha}})$$

$$\stackrel{\triangle}{=} \sum_{\beta=0}^{\alpha} \sum_{i_1, \dots, i_{\alpha}} A(k_1, \dots, k_{\beta}; a_{k_1}, \dots, a_{k_{\beta}})$$

for all i_1, \dots, i_{α} for which $\mu(i_1, \dots, i_{\alpha}; a_{i_1}, \dots, a_{i_{\alpha}})$ is not 0 by hypothesis. For $\alpha = 0$ we have A = x = mean of all

bservations. For $\alpha = 1$ we have $x(i_1; a_{i_1}) = A(i_1; a_{i_2}) + A$ nd therefore $A(i_1; a_{i_1}) = x(i_1; a_{i_1}) - x$. We shall prove by nduction that

$$A(i_1, \dots, i_\alpha; a_{i_1}, \dots, a_{i_\alpha})$$

 $= \sum_{n=1}^{d} (-1)^{\alpha-\beta} \sum_{n=1,\ldots,k} x(k_1,\ldots,k_\beta; a_{k_1},\ldots,a_{k_\beta}).$

Assuming that 5.5 is true for all $\alpha' \leq \alpha$ we proceed to prove 5.5 for $\alpha' = \alpha + 1$. We have

$$x(i_1, \cdots, i_{\alpha+1}; a_{i_1}, \cdots, a_{i_{\alpha+1}})$$

at 3.3 is true for all
$$\alpha \leq \alpha$$
 we proceed to prove $+1$. We have
$$a_1 : a_{i_1} : \cdots : a_{i_{\alpha+1}} : \cdots$$

Hence

(5.6)

$$A(i_1, \dots, i_{\alpha+1}; a_{i_1}, \dots, a_{i_{\alpha+1}})$$

$$= x(i_1, \dots, i_{\alpha+1}; a_{i_1}, \dots, a_{i_{\alpha+1}})$$

$$=x(i_1,\cdots,i_{\alpha+1};a_{i_1},\cdots,a_{i_{\alpha+1}})$$

$$(1, \cdots, T_{\alpha+1}, u_{i_1}, \cdots, u_{i_{\alpha+1}})$$

$$A(i_{1}, \dots, i_{\alpha+1}; a_{i_{1}}, \dots, a_{i_{\alpha+1}})$$

$$= x(i_{1}, \dots, i_{\alpha+1}; a_{i_{1}}, \dots, a_{i_{\alpha+1}})$$

$$- \sum_{\beta=0}^{\alpha} \sum_{i_{1}, \dots, i_{\alpha+1}} A(k_{1}, \dots, k_{\beta}; a_{k_{1}}, \dots, a_{k_{\beta}})$$

$$= x(i_{1}, \dots, i_{\alpha+1}; a_{i_{1}}, \dots, a_{i_{\alpha+1}})$$

$$- \sum_{\beta=0}^{\alpha} \sum_{i_{1}, \dots, i_{\alpha+1}} \sum_{\gamma=0}^{\beta} (-1)^{\beta-\gamma} \sum_{k_{i_{1}}, \dots, k_{\beta}}$$

$$\cdot x(b_1, \dots, b_{\gamma}; a_{b_1}, \dots, a_{b_{\gamma}}).$$

We compute now in 5.6 the coefficient of $x(b_1, \dots, b_r)$; a_{b_1} , \cdots , $a_{b_{\gamma}}$). The term $x(b_1, \cdots, b_{\gamma}; a_{b_1}, \cdots, a_{b_{\gamma}})$ occurs in the last sum for every choice k_1 , k_2 , \cdots , k_{β} which contains b_1 , ..., b_r . Out of the $\alpha+1$ numbers i_1 , ..., $i_{\alpha+1}$ there are for fixed β exactly

$$\binom{\alpha+1-\gamma}{\beta-\gamma}=C_{\beta-\gamma}^{\alpha+1-\gamma}$$

such choices. Hence the coefficient of $x(b_1, \dots, b_{\gamma}; a_{b_1}, \dots, a_{b_{\alpha}})$ becomes

$$-\sum_{\beta=\gamma}^{\alpha} (-1)^{\beta-\gamma} {\alpha+1-\gamma \choose \beta-\gamma} = \sum_{\beta=0}^{\alpha-\gamma} (-1)^{\beta} {\alpha+1-\gamma \choose \beta}$$
$$= (-1)^{\alpha+1-\gamma} - \sum_{\beta=0}^{\alpha+1-\gamma} (-1)^{\beta} {\alpha+1-\gamma \choose \beta}$$
$$= (-1)^{\alpha+1-\gamma}.$$

This proves 5.5.

We show next that the solutions in 5.5 satisfy the restrictions in 5.3. This is clear for $A(1; a_1) = x(1; a_1) - x$. We have by 5.6

$$A(1, \dots, \alpha + 1; a_1, \dots, a_{\alpha+1})$$

$$= x(1, \dots, \alpha + 1; a_1, \dots, a_{\alpha+1})$$

$$- \sum_{\beta=0}^{\alpha} \sum_{1,\dots,\alpha+1} A(k_1, \dots, k_\beta; a_{k_1}, \dots, a_{k\beta}).$$

Summing 5.6a over a_1 and applying mathematical induction we obtain

$$\sum_{a_1} A(1, \dots, \alpha + 1; a_1, \dots, a_{\alpha+1})$$

$$= t_1 \left[x(2, \dots, \alpha + 1; a_2, \dots, a_{\alpha+1}) - \sum_{\beta=0}^{\alpha} \sum_{2, \dots, \alpha+1} A(k_1, \dots, k_\beta; a_{k_1}, \dots, a_{k_\beta}) \right] = 0.$$

by 5.4.

The following argument now shows that the $A(i_1, \dots, i_k; a_{i_1}, \dots, a_{i_k})$ are the unique solutions of the minimum problem. Suppose we wish to minimize the quadratic form

$$Q' = \sum_{a_{i_1}} \cdots \sum_{a_{i_{\alpha}}} \left[x(i_1, \dots, i_{\alpha}; a_{i_1}, \dots, a_{i_{\alpha}}) \right.$$
$$\left. - \sum_{\beta=0}^{\alpha} \sum_{i_1, \dots, i_{\beta}} \mu(k_1, \dots, k_{\beta}; a_{k_1}, \dots, a_{k_{\beta}}) \right]^2$$

under the restrictions 5.3 and no further restrictions. The solution to 5.4 which as we have shown satisfy the restrictions are then the uniquely determined values for which Q' = 0.

Hence if we would write out the least square equations including the terms resulting from the Lagrange operators we should still get the same solutions for the $A(k_1, \dots, k_{\beta})$; $a_{k_1}, \dots, a_{k_{\delta}}$) since Q' can take only one minimum value.

We apply now Theorem 4.2 to our sequence of hypotheses. If $H_h = H_1 \& H_2 \& \cdots \& H_{h-1} \& H_{(i_1, \dots, i_k)}$, then

$$Y_{a_1,\dots,a_r}^{(h-1)} - Y_{a_1,\dots,a_r}^{(h)} = A(i_1,\dots,i_k;a_{i_1},\dots,a_{i_k}).$$

In

$$\sum_{b_1} \cdots \sum_{b_r} (Y_{b_1, \dots, b_r}^{(h-1)} - Y_{b_1, \dots, b_r}^{(h)})^2$$

 $\sum_{b_1}\cdots\sum_{b_r}(Y_{b_{i_1},\ldots,b_r}^{(h-1)}-Y_{b_1,\ldots,b_r}^{(h)}-Y_{b_1,\ldots,b_r}^{(h)})^2$ $\cdot,i_k;a_{i_1},\cdots,a_{i_k}) \text{ occur}$ what is builther. each $A(i_1,\cdots,i_k;a_{i_1},\cdots,a_{i_k})$ occurs $(t_1\cdots t_r)/(t_{i_1}\cdots t_{i_k})$ times. Thus we have by Theorem 4.2

$$\sum_{a_1} \cdots \sum_{a_r} (x_{a_1, \dots, a_r})^2$$

$$= \sum_{\alpha=0}^r \sum_{1, 2, \dots, r} \frac{t_1 \cdots t_r}{t_{i_1} \cdots t_{i_\alpha}} \sum_{a_{i_1}} \cdots \sum_{a_{i_n}}$$

We replace now in the identity 5.7 $x_{a_1 \cdots a_r}$ by

$$= x_{a_1, \dots, a_r} - \sum_{\alpha=0}^{r} \sum_{i_1, \dots, r} \mu(i_1, \dots, i_{\alpha}; a_{i_1}, \dots, a_{i_{\alpha}})$$

$$= \sum_{\alpha=0}^{r} \sum_{i_1, \dots, r} [A(i_1, \dots, i_{\alpha}; a_{i_1}, \dots, a_{i_{\alpha}})]$$
(5.8)

$$-\mu(i_1, \cdots, i_a; a_{i_1}, \cdots, a_{i_a})].$$

But

$$A'(i_1, \dots, i_{\alpha}; a_1, \dots, a_{\alpha}) = [A(i_1, \dots, i_{\alpha}; a_1, \dots, a_{\alpha})]$$

$$-\mu(i_1, \cdots, i_{\alpha}; a_1, \cdots, a_{\alpha})$$

are the uniquely determined values for which

$$z'_{a_1,\dots,a_r} = \sum_{\alpha=0}^r \sum_{1,\dots,r} A'(i_1,\dots,i_{\alpha};a_{i_1},\dots,a_{i_{\alpha}}).$$

Hence from 5.7 we obtain

$$Q = \sum_{a_1} \cdots \sum_{a_r} \left[x_{a_1, \dots, a_r} - \sum_{\alpha} \sum_{1, \dots, r} \mu(i_1, \dots, i_{\alpha}; a_{i_1}, \dots, a_{i_{\alpha}}) \right]^2$$

$$= \sum_{\alpha=0}^{r} \sum_{1, \dots, r} \sum_{a_{i_1}} \cdots \sum_{a_{i_{\alpha}}} \frac{t_1 \cdots t_r}{t_{i_1} \cdots t_{i_{\alpha}}}$$

$$\cdot \left[A(i_1 \underset{\forall w \in \mathcal{W}}{\otimes} d) \hat{j}_{\text{real flowary. or g. flow}} - \mu(i_1, \dots, i_{\alpha}; a_{i_1}, \dots, a_{i_{\alpha}}) \right]^2.$$

Besides testing hypotheses concerning sets of interactions $\mu(i_1, \dots, i_{\alpha}; a_1, \dots, a_{\alpha})$ for all a_1, \dots, a_{α} we may also wish to test hypotheses which concern individual interactions. In such cases certain sets of interactions $\mu(i_1, \dots, i_{\alpha}; a_1, \dots, a_{\alpha})$ will be assumed to be equal to 0 for all a_1, \dots, a_{α} .

We shall refer to such interactions as interactions of type I. Other interactions $\mu(i_1, \dots, i_{\alpha}; a_1, \dots, a_{\alpha})$ will be unknown for all a_1, \dots, a_{α} . These we shall call interactions of type II.

In one such set of interactions, however, we may wish to test hypotheses concerning individual values of the set and we shall call those interactions of type III. Equation 5.9 shows that for finding Q_a and Q_r we must put $\mu(i_1, \dots, i_\alpha; a_1, \dots, a_\alpha) = 0$ for interactions of type I and $\mu(i_1, \dots, i_\alpha; a_1, \dots, a_\alpha) = A(i_1, \dots, i_\alpha; a_1, \dots, a_\alpha)$ for interactions of type II. We then have to minimize for a particular choice j_1, \dots, j_k

$$\sum_{a_1} \cdots \sum_{a_k} [A(j_1, \ldots, j_k; a_1, \ldots, a_k)]$$

$$-\mu(j_1, \cdots, j_k; a_1, \cdots, a_k)]^2$$

with respect to $\mu(j_1\,,\,\cdots\,,j_k\,;a_1\,,\,\cdots\,,\,a_k)$ under the restrictions

$$\sum_{a_k} \mu(j_1, \dots, j_k, \dots, j_k; a_1, \dots, a_n, \dots, a_n) = 0$$

and certain other restrictions imposed by assumption and hypothesis.

As an example consider a three way classification and assume that all 2nd order interactions are 0. We wish to test the hypothesis that all interactions between the first and second classification are 0. The assumption then is

classification are 0. The assumption then is
$$\mu(1, 2, 3; a_1, a_2, a_3) = 0,$$

$$(a_1 = 1, \dots, t_1; a_2 = 1, \dots, t_2; a_3 = 1, \dots, t_3).$$

The hypothesis to be tested is $\mu(1, 2; a_1, a_2) = 0$, $(a_1 = 1, \dots, t_1; a_2) = 0$, $(a_1 = 1, \dots, t_1; a_2)$ deray hypothesis is $(a_1 = 1)(b_2 = 1)$. Clearly Q is minimized under the assumption if we put $\mu(i_1, \dots, i_n; a_{i_1}, \dots, a_{i_n}) = A(i_1, \dots, i_n; a_1, \dots, a_n)$ for $\alpha \leq 2$ and this solution also must satisfy the conditions of 5.3. Similarly to obtain Q_r we put $\mu(i_1, \dots, i_n; a_1, \dots, a_n) = A(i_1, \dots, i_n; a_1, \dots, a_n)$ for all $\mu(i_1, \dots, i_n; a_1, \dots, a_n)$ which are not 0 under the hypothesis. This solution likewise satisfies 5.3. Therefore

$$Q_a = \sum_{a_1} \sum_{a_2} \sum_{a_3} [A(1, 2, 3; a_1, a_2, a_3)]^2,$$

$$Q_r = Q_a + t_3 \sum_{a_1} \sum_{a_2} [A(1, 2; a_1, a_2)]^2.$$

The F statistic for testing the hypothesis is therefore:

$$F = \frac{(t_1 - 1)(t_2 - 1)(t_3 - 1)}{(t_1 - 1)(t_2 - 1)} \cdot \frac{t_3 \sum_{a_1} \sum_{a_2} [A(1, 2; a_1, a_2)]^2}{\sum_{a_1} \sum_{a_2} \sum_{a_3} [A(1, 2, 3; a_1, a_2, a_3)]^2}.$$

Suppose now that under the same assumptions as before we wish to test the hypothesis $\mu(1, 2; 1, 1) = \mu(1, 2; 1, 2)$. To find Q, in this case we would have to minimize

$$[A(1, 2; 1, 1) - \mu(1, 2; 1, 1)]^{2}$$

$$+ [A(1, 2; 1, 2) - \mu(1, 2; 1, 1)]^{2}$$

$$+ \sum_{a_{1}=2}^{t_{2}} \sum_{a_{2}=1}^{t_{2}} [A(1, 2; a_{1}, a_{2}) - \mu(1, 2; a_{1}, a_{2})]^{2}$$

$$+ \sum_{a_{2}=3}^{t_{2}} [A(1, 2; 1, a_{2}) - \mu(1, 2; 1, a_{2})]^{2}$$
Under the restrictions

under the restrictions

e restrictions
www.dbraulibrary.org.in

$$\sum_{a_1} \mu(1, 2; a_1, a_2) = 0, \quad (a_2 = 1, \dots, t_2);$$

 $\sum_{a_2} \mu(1, 2; a_1, a_2) = 0, \quad (a_1 = 1, \dots, t_1)$

$$\sum_{a_1} \mu(1, 2; a_1, a_2) = 0, \qquad (a_1 = 1, \dots, t_1)$$

where $\mu(1, 2; 1, 1) = \mu(1, 2; 1, 2)$.

It is easier to apply the corollary to Theorem 4.3 to the linear form $\mu(1, 2; 1, 1) - \mu(1, 2; 1, 2)$. We then have to find the variance of A(1, 2; 1, 1) - A(1, 2; 1, 2). We have

Variance of
$$A(1, 2; 1, 1) - A(1, 2; 1, 2)$$
. We have
$$A(1, 2; 1, 1)$$

$$= x(1, 2; 1, 1) - x(1; 1) - x(2; 1) + x,$$

$$A(1, 2; 1, 2)$$

$$= x(1, 2; 1, 2) - x(1; 1) - x(2; 2) + x,$$

$$A(1, 2; 1, 1) - A(1, 2; 1, 2)$$

$$= x(1, 2; 1, 1) - x(1, 2; 1, 2) + x(2; 2) - x(2; 1).$$

Remembering that the covariance between two independent quantities is 0 we obtain

$$\begin{split} \sigma_{\{A(1,2;1,1)-A(1,2;1,2)\}}^2 &= \sigma_{x(1,2;1,1)}^2 + 2\sigma_{x(1,2;1,1)x(2;1)} \\ &+ \sigma_{x(1,2;1,2)}^2 - 2\sigma_{x(1,2;1,2)x(2;2)} \\ &+ \sigma_{x(2;2)}^2 + \sigma_{x(2;1)}^2, \end{split}$$

$$\sigma_{(A(1,2;1,1)-A(1,2;1,2))}^2 = 2\sigma^2 \frac{(t_1-1)}{t_1 t_3}.$$

Thus by Theorem 4.1 and 4.3 the F statistic to test the hypothesis $\mu(1, 2; 1, 1) = \mu(1, 2; 1, 2)$ is

$$\begin{split} F &= \frac{(t_1-1)(t_2-1)(t_3-1)}{\text{www.dbraulibraly.org.in}} \frac{t_1 t_3}{2(t_1-1)} \\ &\cdot \frac{\left[A(1,2;1,1)-A(1,2;1,2)\right]^2}{\angle_{a_1} \sum_{a_2} \sum_{a_3} \left[A(1,2,3;a_1,a_2,a_3)\right]^2} \,. \end{split}$$

The identity 5.7 can be generalized to yield

$$\sum_{a_1} \cdots \sum_{a_n} \left[x(i_1, \cdots, i_n; a_{i_1}, \cdots, a_{i_n}) \right]^2$$

$$(5.10) \qquad = \sum_{\beta=0}^{\alpha} \sum_{i_1, \dots, i_{\alpha}} \frac{t_1 \cdots t_{\alpha}}{t_{k_1} \cdots t_{k_{\beta}}} \sum_{a_{k_1}} \cdots \sum_{a_{k_{\beta}}}$$

$$\cdot [A(k_1, \dots, k_\beta; a_{k_1}, \dots, a_{k_\beta})]^2.$$

To prove 5.10 we note that $x(i_k, \dots, i_{k\beta}; a_{k_1}, \dots, a_{k\beta})$ may be regarded as the mean of all $x(i_1, \dots, i_n; a_{i_1}, \dots, a_{i_n})$ with fixed $a_{k_1}, \dots, a_{k\beta}$. Applying then the identity 5.9 to the quantities $x(i_1, \dots, i_n; a_1, \dots, a_n)$ yields 5.10, since the quantities $A(k_1, \dots, k_{\beta}; a_{k_1}, \dots, a_{k\beta})$ in 5.10 are defined in

terms of the $x(i_1, \dots, i_n; a_{i_n}, \dots, a_{i_n})$.

To facilitate the computation of sums of squares of interactions we shall prove

$$\sum_{a_1} \cdots \sum_{a_k} [A(i_1, \dots, i_k; a_{i_1}, \dots, a_{i_k})]^2$$

$$= \sum_{\alpha=0}^k (-1)^{k-\alpha} \sum_{i_1, \dots, i_k} \sum_{a_{j_1}} \cdots \sum_{a_{j_\alpha}} \frac{t_{i_1} \cdots t_{i_k}}{t_{i_1} \cdots t_{i_\alpha}}$$

$$\cdot [x(j_1, \dots, j_\alpha; a_{i_1}, \dots, a_{i_\alpha})]^2.$$

For instance

$$\begin{split} & \cdot [x(j_1\;,\,\cdots\;,\,j_\alpha\;;\,a_{i_1}\;,\,\cdots\;,\,a_{i_\alpha})]^2. \end{split}$$
 For instance
$$\sum_{a_1} \cdots \sum_{a_s} [A(1,\;2,\;3;\,a_1\;,\,a_2\;,\,a_3)]^2 \\ &= \sum_{a_1} \sum_{a_s} \sum_{a_s} [x(1,\;2,\;3;\,a_1\;,\,a_2\;,\,a_3)]^2 \\ & - t_1 \sum_{a_2} \sum_{a_s} [x(2,\;3;\,a_2\;,\,a_3)]^2 \\ & - t_2 \sqrt{\sum_{a_1}} db \sum_{a_3} u[t(1;a_3;\,a_1,\,a_2)]^2 \\ & - t_3 \sum_{a_1} \sum_{a_2} [x(1,\;2;\,a_1\;,\,a_2)]^2 \\ & + t_1 t_2 \sum_{a_3} [x(3;\,a_3)]^2 + t_1 t_3 \sum_{a_s} [x(2;\,a_2)]^2 \\ & + t_2 t_3 \sum_{a_1} [x(1;\,a_1)]^2 - t_1 t_2 t_3 x^2. \end{split}$$

We shall prove 5.11 by induction. We have

$$A^{2} = x^{2},$$
 $\sum_{a_{1}} [A(i_{1}; a_{1})]^{2} = \sum_{a_{1}} [x(i_{1}; a_{1}) - x]^{2}$
 $= \sum_{a_{1}} [x(i_{1}; a_{1})]^{2} - t_{1}x^{2}.$

Suppose that 5.11 is true for k' < k. From 5.10 we have

$$\sum_{a_{i_1}} \cdots \sum_{a_{i_k}} [A(i_1, \dots, i_k; a_{i_1}, \dots, a_{i_k})]^2$$

$$= \sum_{a_{i_1}} \cdots \sum_{a_{i_k}} [x(i_1, \dots, i_k; a_{i_1}, \dots, a_{i_k})]^2$$

$$- \sum_{\alpha=0}^{k-1} \sum_{i_1, \dots, i_k} \frac{t_{i_1} \cdots t_{i_k}}{t_{k_1} \cdots t_{k_{\alpha}}} \sum_{a_{k_1}} \cdots \sum_{a_{k_{\alpha}}} \cdot [A(k_1, \dots, k_{\alpha}; a_{k_1}, \dots, a_{k_{\alpha}})]^2.$$

Applying 5.11 to 5.12 for $\alpha < k$ we find

$$\sum_{a_{i_1}} \cdots \sum_{a_{i_k}} \left[A(i_1, \cdots, i_k; a_{i_1}, \cdots, a_{i_k}) \right]^2$$

$$= \sum_{a_{i_1}} \cdots \sum_{a_{i_k}} \left[x(i_1, \cdots, i_k; a_{i_1}, \cdots, a_{i_k}) \right]^2$$

$$- \sum_{a=0}^{k-1} \sum_{i_1, \cdots, i_k} \frac{t_{i_1} \cdots t_{i_k}}{t_{k_1} \cdots t_{k_n}} \sum_{\beta=0}^{\alpha} (-1)^{\alpha-\beta}$$

$$\cdot \sum_{k_1, \cdots, k_n} \sum_{a_{j_1}} \cdots \sum_{a_{i\beta}} \frac{t_{k_1} \cdots t_{k_n}}{t_{j_1} \cdots t_{j\beta}}$$

$$\cdot \left[x(j_1, \cdots, j_\beta; a_{j_1}, \cdots, a_{j_\beta}) \right]^2.$$
The term

 $\cdot [x(j_1\ ,\ \cdots\ ,j_{eta}\ ;a_{i_1}\ ,\ \cdots\ ,a_{i_{eta}})]^2.$ www.dbraulibrary.org.in The term

$$[x(j_1, \dots, j_{\beta}; a_{i_1}, \dots, a_{i_{\beta}})]^2 \frac{t_{i_1} \dots t_{i_k}}{t_{i_1} \dots t_{i_{\beta}}}$$

occurs in this expansion as often as we can make a choice of the indices j_1 , ..., j_{β} out of indices k_1 , ..., k_{α} with $\beta \leq$ $\alpha < k$. Since the indices j_1 , ..., j_{β} are fixed, there remain $k - \beta$ indices to choose from. With α fixed there are then $\alpha - \beta$ indices to choose out of $k - \beta$ indices. Hence for the fixed α the term

$$x(j_1, \dots, j_{eta}; a_{i_1}, \dots, a_{i_{eta}}) \frac{t_{i_1} \dots t_{i_{lpha}}}{t_{i_1} \dots t_{i_{eta}}}$$

$${k-eta \choose lpha-eta} = C_{lpha-eta}^{k-eta}$$

times. Hence its coefficient becomes

$$-\sum_{\alpha=\beta}^{k-1} (-1)^{\alpha-\beta} \binom{k-\beta}{\alpha-\beta} = -\sum_{l=0}^{k-\beta-1} (-1)^{l} \binom{k-\beta}{l}$$

$$= -\sum_{l=0}^{k-\beta} (-1)^{l} \binom{k-\beta}{l} + (-1)^{k-\beta}$$

$$= (1-1)^{k-\beta} + (-1)^{k-\beta}.$$

Substituting this result in 5.13 we obtain 5.11.

An important special case arises if in an r-way classification design we do not take one but several observations in every one of the multiple classifications. Such a design may be treated as an (r+1) way classification design by simply numbering the variables in every subclass in an arbitrary manner. We shall then be justified in assuming that the (r+1)st classification has no effect on the mean value. Or $\mu(i_1, \dots, i_k, r+1; a_{i_1}, \dots, a_{i_k}, a_{r+1}) = 0$ for all choices $i_1 < \dots < i_k < r+1$. We then have from 5.9

$$Q_{a} = \sum_{\alpha=0}^{r} \sum_{1,\dots,r} \frac{t_{i} \cdots t_{r}t_{r+1}}{t_{i_{1}} \cdots t_{i_{\alpha}}} \sum_{a_{i_{1}}} \cdots \sum_{a_{i_{\alpha}}} \sum_{a_{r+1}} \cdots \left[A(j_{1}, \dots, j_{a_{w}}, \text{dibiadilibration or } a_{r+1})^{2} \right]^{2}$$

$$= \sum_{a_{1}} \cdots \sum_{a_{r+1}} \left[x(1, \dots, r+1; a_{1}, \dots, a_{r+1}) \right]^{2}$$

$$= \sum_{a_{1}} \cdots \sum_{a_{r+1}} \sum_{\alpha} \sum_{1,\dots,r} \frac{t_{1} \cdots t_{r}}{t_{j_{1}} \cdots t_{j_{r}}} \sum_{a_{i_{1}}} \cdots \sum_{a_{j_{\alpha}}} \cdots \sum_{a_{j_{\alpha}}} \cdots \sum_{a_{j_{\alpha}}} \left[A(j_{1}, \dots, j_{\alpha}; a_{i_{1}}, \dots, a_{i_{\alpha}}) \right]^{2}$$

$$= \sum_{a_{1}} \cdots \sum_{a_{r+1}} \left[x(1, \dots, r+1; a_{1}, \dots, a_{r+1}) \right]^{2}$$

$$= \sum_{a_{1}} \cdots \sum_{a_{r+1}} \left[x(1, \dots, r, r+1; a_{1}, \dots, a_{r}) \right]^{2}$$

$$= \sum_{a_{1}} \cdots \sum_{a_{r+1}} \left[x(1, \dots, r, r+1; a_{1}, \dots, a_{r}) \right]^{2}$$

$$= \sum_{a_{1}} \cdots \sum_{a_{r+1}} \left[x(1, \dots, r, r+1; a_{1}, \dots, a_{r}) \right]^{2}$$

Formula 5.14 is easy to interpret. Since the distribution of $x_{a_1} ... a_{rar+1}$ is independent of a_{r+1} by assumption we obtain an estimate of the common variance from the sums of squares of deviations from the means of the observations in each subclass. The number of degrees of freedom of this estimate is

. a our asst . g to 5.14 derive . heses. $\text{for all } a_1 \ , a_2 \ .$ $. (a_1) = 0 \quad \text{ for all } a_1 \ , a_2 \ .$ www.dbraulibrary.org.in

CHAPTER VI

The Power of the Analysis of Variance Test

We are considering a situation in which we know apriori that the cumulative distribution function of the random variables x_1, \dots, x_n is given by a function

(6.1)
$$f(x_1, \dots, x_n, \theta_1, \dots, \theta_r).$$

We wish to test the hypothesis that certain of the parameters θ have certain specified values which for convenience we may assume to be 0.

The hypothesis may then be formulated as follows

$$H: {}_{\text{www.dbraulibratey.torg}}$$
in

We test this hypothesis in the following way. Suppose it is possible to determine a region W in the n dimensional space R_n in such a way that the probability that a sample x_1, \dots, x_n will fall into W is a fixed constant α provided the hypothesis H is true, in symbols $P(x_1, \dots, x_n \subset W \mid H) = \alpha$. The number α is called the level of significance of the test or the size of W. We then decide to take a sample x_1, \dots, x_n and to reject the hypothesis H if the point x_1, \dots, x_n lies in W.

If the point x_1 , \dots , x_n does not lie in W we either accept H as true or make further investigations. These investigations may consist in taking a larger sample if the distribution in the larger sample depends also on θ_1 , \dots , θ_s . The fact that the region W has a fixed size if H is true assures us that, provided H is true, we shall in the long run make a wrong decision only in α of the cases, where we draw a sample. This alone is however quite insufficient to make the test valuable. An example will illustrate this. Suppose $\alpha = .05$ and we put numbers from 1 to 20 into an urn and test every hypothesis by drawing a number from our urn. We reject the hypothesis H whenever the number I is drawn. Otherwise we do not reject it. Obviously the probability of rejecting H when H is true is $\alpha = .05$.

Nevertheless the test is obviously of no value. The reason for this is that the probability of rejecting H when H is false is also only .05. Thus the test does not discriminate between H and situations different from H.

We shall denote by $P(E \mid H)$ the probability that E will happen computed under the assumption that H is true. Let us consider another alternative situation H' and denote the ibrary.ord point x_1 , ..., x_n by x. Then

$$(6.3) P(x \subset W \mid H) = \alpha$$

is called the size of the critical region W and

$$(6.4) P(x \subset W \mid H')$$

is called the power of the critical region W with respect to the alternative situation H'. The power $P(x \subset W \mid H')$ is the probability of discovering that H^{\prime} not true provided that H^{\prime} is true. It is thus a function of the alternative H'. If

$$(6.5) P(x \subset W \mid H') \geq P(x \subset W' \mid H')$$

for all regions W' for which

$$(6.6) P(x \subset W' \mid H) = \alpha$$

then W is called a most powerful region of size α with respect to the alternative H'. If there exists a region which is most powerful with respect to all alternatives then it is clear that this region is superior to all other regions.

Unfortunately most powerful regions with respect to all alternatives do rarely exist. Thus the choice of the critical region has to be made on the basis of some compromise principle. It seems for instance reasonable to require that

$$I: P(x \subset W \mid H') \geq \alpha$$

for all H'. A region which fulfills (6.3) and I is called an unbiased critical region of size a. If it also fulfills (6.5) for all regions W' which satisfy (6.3) and I, then it is called a most powerful unbiased region of size α. Most powerful unbiased regions do also rarely exist.

DISTY.ON

It may be seen from the foregoing discussion that a knowledge of the power function $P(x \subset W \mid H') = f(H')$ is indispensable if we want to know what a test really accomplishes and we shall, therefore, in this chapter derive the power function of the analysis of variance tests.

In chapter one we have shown that the statistic F is computed from the ratio of two chi square expressions.

$$\chi_1^2 = \frac{x_1^2 + \cdots + x_{n_1}^2}{\sigma^2}$$
,

$$\chi_2^2 = \frac{y_1^2 + \cdots + y_{n_2}^2}{\sigma^2}$$
,

where x_1 , ..., x_{n_1} ; y_1 , ..., y_{n_2} were assumed to be independently and normally distributed variables with means 0 and variance σ^2 . If x_1 , ..., x_n , have variance σ^2 and y_1 , ..., y_{n_2} variance σ^2 there are two essentially different hypotheses that may be tested by means of the F statistic: the hypothesis $H_1: \sigma_1^2 = \sigma_2^2$ under the assumption $E(x_i) = E(y_i) = 0$ and the hypothesis $H_2: E(y_i) = 0$ under the assumption $\sigma_1^2 = \sigma_2^2$ and $E(x_i) = 0$. We shall be chiefly concerned with the hypothesis H_2 .

In chapter IV we discussed tests of linear hypotheses. In proving theorem 4.1 we have shown that the F ratio was given by

$$F = \frac{n_1}{n_2} \frac{\chi_2^2}{\chi_1^2}$$
, $\chi_2^2 = \frac{y_1^2 + \cdots + y_{n_2}^2}{\sigma^2}$, $\chi_1^2 = \frac{x_1^2 + \cdots + x_{n_1}^2}{\sigma^2}$,

where the assumption stated that

(6.7)
$$E(x_i) = 0, \quad (i = 1, \dots, n_i).$$

The hypothesis to be tested was

(6.8)
$$E(y_i) = 0, \quad (i = 1, \dots, n_2).$$

Thus the alternatives to be considered are of the form

$$(6.9) H': E(y_i) = \theta_i.$$

The critical region W for testing H was given by $F \geq \overline{F}$. To find the power of the test it is therefore necessary to compute the distribution of

(6.10)
$$\chi'^2 = \frac{y_1^2 + \cdots + y_{n_1}^2}{\sigma^2}$$

under the assumption that the y, are normally distributed with mean value θ_i and common variance σ^2 . We then have Kary,o to derive the distribution of

(6.11)
$$F' = \frac{{\chi'}^2}{\chi_1^2} .$$

The power of the test will then be given by $P(F' \geq n_2/n_1|\widehat{F})$. Our problem will be solved if we find the distribution of F'. For our evaluation of (6.11) it is necessary to bring the linear hypothesis first into the form (6.7) and (6.8) by applying the transformations discussed in the proof of Theorem (4.1).

In the derivation of the distribution of χ'^2 we shall need the function $\Gamma(z)$ as defined in chapter one and the function

(6.12)
$$B(n, m) = \int_0^1 x^{n-1} (1-x)^{m-1} dx.$$

The Γ function satisfies the relations $\Gamma(n) = (n-1)\Gamma(n-1)$, $\Gamma(1) = 1$, and $\Gamma(\frac{1}{2}) = \pi^{1}$. Between the Γ and the β function the following relation helds

(6.13)
$$B(n, m) = \frac{\Gamma(m)\Gamma(n)}{\Gamma(n+m)}.$$

To prove this relation we compute

$$\Gamma(m)\Gamma(n) = \int_0^\infty x^{n-1}e^{-x} dx \int_0^\infty y^{m-1}e^{-y} dy$$

$$= \int_0^\infty \int_0^\infty e^{-(x+y)}x^{n-1}y^{m-1} dx dy.$$

We make the substitution

$$(6.14) y = u(1-z), x = uz.$$

Its Jacobian is u. The region $0 \le x < \infty$, $0 \le y < \infty$ is transformed into $0 \le u < \infty$, $0 \le z < 1$. Hence

$$\Gamma(m)\Gamma(n) = \int_0^{\infty} e^{-u} u^{n+m-1} du \int_0^1 z^{n-1} (1-z)^{m-1} dz$$
$$= \Gamma(m+n)B(n, m).$$

This proves (6.13).

We proceed to derive the distribution of χ'^2 . We know that χ'^2 is the sum of, say, r squares of random variable z_1 , \cdots , z_r which are independently and normally distributed with common variance σ^2 and means $d_{abraulib}d_{ary}$ The joint distribution of z_1, \dots, z_r is thus given by

(6.15)
$$p(z_1, \dots, z_r) = \frac{1}{(2\pi)^{r/2}\sigma^r} \exp\left[-\frac{1}{2\sigma^2} \sum_i (z_i - d_i)^2\right].$$

Putting

$$\lambda = \frac{1}{2\sigma^2} \sum_{i} d_i^2$$

equation (6.15) may be written as

(6.17)
$$p(z_1, \dots, z_r) = \frac{e^{-\lambda}}{(2\pi)^{r/2} \sigma^r} \exp\left(-\frac{1}{2\sigma^2} \left[\sum_i z_i^2 - 2\sum_i z_i d_i\right]\right).$$

We now put

$$W_1 = \left(\sum_i d_i^2\right)^{-\frac{1}{2}} \sum_i z_i d_i = \sum_i z_i d_i' ,$$
(6.18)

$$W_i = \sum_{i=1}^r a_{ii}z_i, \qquad (i=2, \dots, r),$$

where the matrix

$$T = \begin{pmatrix} d'_1 & \cdots & d'_r \\ a_{21} & \cdots & a_{2r} \\ \vdots & & \vdots \\ \vdots & & \ddots \\ \vdots & & \ddots \\ a_{r1} & \cdots & a_{rr} \end{pmatrix}$$

is orthogonal and assume r > 1. We then have

$$E(W_i) = (\sum_i d_i^2)^{\frac{1}{i}},$$
6.19)

$$\chi'^2 = \frac{1}{2} \sum_{\text{www.dbraudibrat}} z_{\text{torg}}^2 = \frac{1}{\sqrt{2}} \sum_{i} W_i^2$$

 $E(W_i) = 0, \qquad (i = 2, \cdots, r)$ because of the orthogonality of T. Furthermore $\chi^{\prime 2} = \frac{1}{\sqrt{2}} \sum_{w \in W} z_i^2 = 1$ Since T is 0^{-1} . distributed with common variance σ^2 and

(6.20)
$$\frac{1}{\sigma^2} \sum_{i=1}^{n} W_i^2 = \chi^2$$

has the χ^2 distribution with (r-1) degrees of freedom given by (1.2). The joint distribution of χ^2 and W_1 is therefore given by the density function

by the density function
$$P(\chi^{2}, W_{1}) = \frac{e^{-\lambda}}{(2\pi)^{1/2} 2^{(r-1)/2} \Gamma([r-1]/2) \sigma} (\chi^{2})^{(r-3)/2}$$

$$(6.21)$$

$$\cdot \exp\left(-\frac{1}{2\sigma^{2}} [\sigma^{2}\chi^{2} + W_{1}^{2} - 2\sigma W_{1}(2\lambda)^{1/2}]\right)$$

To obtain the distribution of

(6.22)
$$\chi'^2 = \frac{W_1^2}{\sigma^2} + \chi^2$$

we put

(6.23)
$$\chi^2 = \chi'^2 \cos^2 \theta, \quad \frac{W_1}{\sigma} = \chi' \sin \theta.$$

The Jacobian of this transformation becomes

$$\begin{vmatrix} \cos^2 \theta & -\chi'^2 \sin 2\theta \\ \frac{\chi' \sigma^1 \sin \theta}{2} & \sigma \chi' \cos \theta \end{vmatrix} = \sigma \chi' \cos \theta$$

and to the region $0 \le \chi^2 < \infty$, $-\infty \le W_1 < \infty$ corresponds the region $0 \le \chi'^2 < \infty$, $-\pi/2 \le \theta \le \pi/2$. Thus the joint distribution of χ'^2 and θ is given by the density function.

(6.24)
$$Q(\chi'^{2}, \theta) = \frac{e^{-\lambda}}{\pi^{1/2} 2^{r/2} \Gamma([r-1]/2)} (\chi'^{2})^{(r-2)/2} (\cos \theta)^{r-2} \exp\left[-\frac{1}{2} (\chi'^{2} - 2(2\lambda)^{1/2} \chi' \sin \theta)\right].$$

If we integrate this expression with respect to θ from $-\pi/2$ to $\pi/2$ we shall obtain the distribution of (χ'^2) . To perform this integration we expand exp $[+(2\chi\chi'^2)^2]$ sin θ] into a series. Since for m odd

$$\int_{-\pi/2}^{\pi/2} \cos^{r-2} \theta \sin^{m} \theta \, d\theta = 0$$

we obtain

we obtain
$$\int_{-\pi/2}^{\pi/2} \cos^{r-2} \theta \exp \left[(2\lambda \chi'^2)^{1/2} \sin \theta \right] d\theta$$
(6.25)
$$= \sum_{m=0}^{\infty} \frac{(2\lambda \chi'^2)^m}{(2m)!} \int_{-\pi/2}^{\pi/2} \cos^{r-2} \theta \sin^{2m} \theta d\theta.$$
We have
$$\int_{-\pi/2}^{\pi/2} \cos^{r-2} \theta \sin^{2m} \theta d\theta = \int_{-1}^{1} (1 - u^2)^{(r-3)/2} (u^2)^m du.$$

$$\int_{-\pi/2}^{\pi/2} \cos^{r-2} \theta \sin^{2m} \theta \, d\theta = \int_{-1}^{1} (1 - u^2)^{(r-3)/2} (u^2)^m \, du$$

$$= \int_{0}^{1} (1 - v)^{(r-3)/2} v^{m-(1/2)} \, dv$$

$$= B\left(\frac{r-1}{2}, m + \frac{1}{2}\right)$$

$$= \frac{\Gamma([r-1]/2)\Gamma(m+1/2)}{\Gamma(r/2+m)}.$$

On the other hand

$$(2m)! = (2m)(2m-1) \cdots 3 \cdot 2 \cdot 1$$

$$= 2^{m} m! (2m-1)(2m-3) \cdots 5 \cdot 3 \cdot 1$$

$$= \frac{2^{2m} m!}{\Gamma(\frac{1}{2})} \left(\frac{2m-1}{2} \cdot \frac{2m-3}{2} \cdots \frac{5}{2} \cdot \frac{3}{2} \cdot \Gamma(\frac{1}{2}) \right)$$

$$= \frac{2^{2m} m!}{\pi^{1/2}} \Gamma(m+\frac{1}{2}).$$

Hence

$$= \frac{2^{2m}m!}{\Gamma(\frac{1}{2})} \left(\frac{2m-1}{2} \cdot \frac{2m-3}{2} \cdot \cdot \cdot \frac{3}{2} \cdot \cdot \frac{3}{2} \cdot \cdot \cdot \left(\frac{1}{2}\right)\right)$$

$$= \frac{2^{2m}m!}{\pi^{1/2}} \Gamma\left(m + \frac{1}{2}\right).$$
Hence
$$\int_{-\pi/2}^{\pi/2} \cos^{r-2}\theta \exp\left[\left(2\lambda\chi'^2\right)^{1/2} \sin\theta\right] d\theta$$

$$= \sum_{m=0}^{\infty} \left(\frac{\lambda\chi'^2}{2}\right)^m \frac{\Gamma(\{p-1\}/2)\pi^{1/2}}{m!\Gamma(r/2+m)}$$

$$= \pi^{1/2}\Gamma\left(\frac{r-1}{2}\right) \sum_{m=0}^{\infty} \frac{(\lambda\chi'^2/2)^m}{m!\Gamma(r/2+m)}.$$
Thus the distribution of χ'^2 is given by its density function
$$Q(\chi'^2)$$

Thus the distribution of χ'^2 is given by its density function

For $\lambda = 0$ equation (6.27) reduces to the χ^2 distribution 1.2 as it should. It is not difficult to verify that 6.27 also holds for r = N

We now proceed to derive the distribution of $G = \chi'^2/\chi^2$ where χ'^2 and χ^2 are independent and χ^2 has the χ^2 distribution with s degrees of freedom. The joint probability density of χ^2 and ${\chi'}^2$ is given by

$$P(\chi^{2}, \chi'^{2}) = \frac{e^{-\lambda}}{4\Gamma(s/2)} \left(\frac{\chi'^{2}}{2}\right)^{(r-2)/2} \left(\frac{\chi^{2}}{2}\right)^{(s-2)/2} \cdot \exp\left(-\frac{1}{2}(\chi'^{2} + \chi^{2})\right) \sum_{m=0}^{\infty} \frac{\lambda^{m}(\chi'^{2}/2)^{m}}{m!\Gamma(r/2 + m)}.$$

We make the substitution

$$\chi'^2 = \frac{Gz}{1+G}, \qquad \chi^2 = \frac{z}{1+G}.$$

The Jacobian of this substitution is $z/(1+G)^2$. Thus the joint distribution of z/2 and G is given by its density function:

$$q\left(\frac{z}{2}, G\right) = e^{-\lambda} \left(\frac{G}{1+G}\right)^{(\tau-2)/2} \left(\frac{1}{1+G}\right)^{(s+2)/2} e^{-(s/2)}$$

$$\cdot \sum_{m=0}^{\infty} \left(\frac{G}{1+G}\right)^m \frac{\lambda^m (z/2)^{(s+s+2m-2)/2}}{m! \Gamma(z/2+m) \Gamma(s/2)}.$$

Integrating out with respect to z we obtain the density of the distribution of G.

(6.29)
$$P(G) = \sum_{m=0}^{\infty} e^{-\lambda} \left(\frac{G}{1+G}\right)^{(r+2m-2)/2} \left(\frac{1}{1+G}\right)^{(s+2)/2} \cdot \frac{\lambda^m \Gamma([r+s]/2+m)}{m! \Gamma(r/2+m) \Gamma(s/2)}$$

or on account of (6.13)

(6.30)
$$P(G) = \sum_{m=0}^{\infty} e^{-\lambda} \left(\frac{G}{1+G}\right)^{(r+2m-2)/2} \left(\frac{1}{1+G}\right)^{(s+2)/2} \frac{\lambda^m}{m!} \cdot \left[B\left(\frac{r}{2}+m,\frac{s}{2}\right)\right]^{-1}.$$

Let \overline{F}_{α} be the critical value of F for the level of significance α so that $P(F \geq \overline{F}_{\alpha} \mid \lambda = 0) = \alpha$. Put r/s $\overline{F}_{\alpha} = \overline{G}_{\alpha}$. P. C. Tang (Statistical Research Memoirs V.2, 1938) has tabulated the integrals

(6.31)
$$\int_0^{\tilde{\sigma}_{***}} P(G) \ dG, \qquad \int_0^{\tilde{\sigma}_{***}} P(G) \ dG$$

for various values of $\Phi = [2\lambda/(r+1)]^{\frac{1}{2}}$ and various degrees of freedom. This integral represents the probability P_{II} that

we shall fail to reject the hypothesis $\theta_{***} = \cdots = \theta_{***} = 0$ although it is false and some alternative $\theta_{***} = d_i$, \vdots , \vdots , $\theta_{****} = d_r$ is true for which

$$\lambda = \frac{\sum d_i^2}{2\sigma^2}$$

Thus one obtains an excellent picture of what the F -test will accomplish. Tang's tables must also be consulted if it is desired to find the sample size necessary to discover alternatives with specified values of λ with a given probability.

The evaluation of (6.30) and (6.31) requires the knowledge of λ and σ^2 but we may use $\overline{\sigma}^2 = (Q_{\sigma})/s$ as an estimate of σ^2 .

The assumptions of a linear hypothesis state that the given normally and independently distributed random variables x_1 , ..., x_n have the same variance and means μ_1 , ..., μ_n satisfying the relations μ_1, \dots, μ_n deraulibrary orgain

(6.32)
$$\sum_{i=1}^{n} c_{ii} \mu_{i} = 0, \quad (i = 1, \dots, s), \quad \text{rank } (c_{ii}) = s.$$

The hypothesis then states that

(6.33)
$$\sum_{i} c_{s+i,i} \mu_{i} = 0$$
, $(i = 1, \dots, r)$, rank $\begin{pmatrix} c_{ii} \\ c_{s+i,i} \end{pmatrix} = s + r$.

Lemma 4.1 shows that we may assume that the c_{ij} are the first r + s rows of an orthogonal matrix. Hence

(6.34)
$$\sum_{i=1}^{n} (x_i - \mu_i)^2 = \sum_{j=1}^{n} \left[\sum_{i=1}^{n} c_{ij}(x_j - \mu_i) \right]^2$$

and therefore

$$Q_r - Q_a = \sum_{i=1}^{s+r} \left[\sum_{i=1}^{n} c_{ij} x_i \right]^2.$$

Suppose now that the alternative H' states that $E(x_i) = \overline{\mu_i}$ where the $\overline{\mu_i}$ fulfill the relations (6.32) but

$$(6.36) \quad \sum_{i} c_{s+i,i} \overline{\mu}_{i} = d_{i}, \quad (i = 1, \dots, r), \quad \sum_{i} d_{i}^{2} > 0.$$

Then

(6.37)
$$2\sigma^2 \lambda = \sum_{i} d_i^2 = \sum_{i=s+1}^{r+s} \left[\sum_{j=1}^{n} c_{ij} \vec{\mu}_i \right]^2.$$

Comparing (6.35) and (6.37) we see that we may obtain $2\sigma^2\lambda$ simply by substituting into the expression for $Q_r - Q_a$ the values $\overline{\mu}_i$ for x_i . This simple rule is particularly useful since the alternative is mostly stated in terms of the mean values of x_i and not in terms of the linear functions (6.33) of these mean values.

To illustrate the use of Tang's tables we consider testing the row effects in a k by m two way classification design (example 4 of Chapter 4). The assumption was formulated in the form

(6.38)
$$E(x_{ij}) = \mu_i + \mu_{ij} + \lambda_i$$

$$- \text{www.dbraulibrary.org.in}$$

with $\sum_{i} \mu_{i} = \sum_{i} \mu_{i} = 0$. The hypothesis to be tested was

(6.39)
$$H: \mu_i = 0, \quad (i = 1, \dots, k).$$
 We obtained

We obtained

(6.40)
$$Q_r - Q_a = m \sum_i (x_i - x)^2, \quad x_i = \frac{1}{m} \sum_i x_{ij}.$$

Consider now the alternative H':

(6.41)
$$E(x_{ij}) = \theta_i + \mu_{ij} + \mu_i \sum_i \theta_i = 0, \sum_i \theta_i^2 > 0.$$

Then $E(x_i) = \theta_i + \mu$, $E(x) = \mu$.

Applying our rule we have to substitute in (6.40) for x_{ij} the expression $\theta_i + \mu_{i,j} + \mu_i$. Hence for x_i , we have to substitute $\theta_i + \mu_i$ Thus

$$(6.42) 2\sigma^2\lambda = m \sum_i \theta_i^2.$$

The quantity

$$\frac{1}{m} \Phi^2 = \frac{\sum_i \theta_i^2}{k \sigma^2}$$

can be interpreted as the mean square of the row effects expressed as a multiple of the variance. Suppose for instance that this mean square is .8 σ^2 and that m=5; then $\Phi=2$. If k=4 then the degrees of freedom for Q_s are (k-1) (m-1)=12. In Tang's tables* we find that for 3 and 12 degrees of freedom respectively and for $\Phi=2$ the probability P_{11} of not rejecting the null hypothesis is .463 if a 1% level of significance is used and .178 if a 5% level of significance is used. That is to say: If we use a 5% level of significance, we shall, in more than 82 cases out of 100 reject the hypothesis $\theta_i=0$ (i=1,2,3,4) if the mean square of the row effects is at least .8 times the variance.

Tang's tables do not only give us very valuable information about the results to be expected from analysis of variance tests but enable us also to find the number of experiments necessary to achieve vertail results. Suppose for instance that we plan a two way classification design with, if necessary, more than I experiment in each subclass. We wish to test on a 1% level of significance whether the interaction between the two classifications is 0. We are interested in alternatives for which the mean square of the interactions is at least .16 times the variance and we want to take a large enough sample to uncover such alternatives in at least 50% of the experiments.

Our assumption then is

$$\mu(1, 2, 3; i, j, k) = \mu(1, 3; i, k)$$
$$= \mu(2, 3; j, k) = \mu(3; k) = 0$$

for $i = 1, \dots, t_1$; $j = 1, \dots, t_2$; $k = 1, \dots, t_3$. By (5.14) $Q_a = \sum_i \sum_i \sum_k [x(1, 2, 3; i, j, k) - x(1, 2; i, j)]^2$ with $t_i t_2(t_3 - 1)$ degrees of freedom. From (5.9) we find $Q_i - Q_a = t_2 \sum_i \sum_i [A(1, 2; i, j)]^2$ with $(t_1 - 1)(t_2 - 1)$ degrees of freedom. Thus if $\mu(1, 2; i, j) = d_{ij}$ we obtain

$$2\sigma^2\lambda = t_3 \sum_i \sum_i (d_{ij})^2$$

^{*}The degrees of freedom of the numerator are, in Tang's tables, denoted by f_1 ; those of the denominator by f_2 . The quantity $E^2{}_a = G_a/(1 + G_a)$.

and

$$\Phi^{2} = \frac{2\lambda}{(t_{1} - 1)(t_{2} - 1) + 1}$$

$$= \frac{t_{1}t_{2}t_{3}}{(t_{1} - 1)(t_{2} - 1) + 1} \frac{\sum_{i} \sum_{j} (d_{ij})^{2}}{\sigma^{2}t_{1}t_{2}}.$$

We are interested only in alternatives for which

We are interested only in alternatives for which
$$\frac{\sum_{i}\sum_{j}\left(d_{ij}\right)^{2}}{\sigma^{2}t_{1}t_{2}}\geq .16 \quad \text{or} \quad \Phi^{2}\geq .16\frac{t_{1}t_{2}t_{3}}{(t_{1}-1)(t_{2}-1)+1}.$$
 Suppose now that $t_{1}=2,t_{1}=5$ then $\Phi^{2}\geq .22$ t. We reproduce

Suppose now that $t_1=2,\,t_2=5$ then $\Phi^2\geq .32\,t_3$. We reproduce below the relevant part of Tang's table for $f_1 = 4$ and a 1% level of significance. We find $P_{\rm H}$ as follows

$$f_2$$
 1.5 2.0 2.5 2.5 30 $.570$ $.225$ $.044$ 60 $.509$ $.165$ $.024$,

For $t_3 = 6$ we have $\Phi^2 = 1.92$, $f_2 = 50$ and this would not be enough to insure that $1 - P_{II} \ge 50\%$. For $t_3 = 7$ we have $\Phi^2 = 2.24$, $f_2 = 60$ and P_{II} is approximately .51.

Although Tang's results give a good picture of the discriminating power of analysis of variance tests, the question arises whether other tests could not accomplish more than the analysis of variance test does. Generally one does not know the alternatives and it is not possible to maximize the power with respect to every possible alternative. Therefore it will be the aim of the investigator to maximize some average of the power. A. Wald has shown that the analysis of variance test has such an optimum property. (Ann. Math. Stat. Vol.13 #4).

In Chapter four it was shown that tests of linear hypotheses can be brought into the following form. The variables

$$x_1, \dots, x_r; y_1, \dots, y_s, y_{s+1}, \dots, y_s$$

are normally and independently distributed with common variance σ^2 . It is known that $E(x_i) = 0$, $(i = 1, \dots, r)$. The hypothesis to be tested is

(6.43)
$$E(y_i) = 0, \quad (i = 1, \dots, s).$$

The critical region W_0 in the analysis of variouse test is defined by

(6.44)
$$G = \frac{n_2}{n_1} F = \frac{y_1^2 + \dots + y_n^2}{x_1^2 + \dots + x_n^2} \ge C.$$

That is to say the hypothesis (4.43) will be rejected if $G \geq C$. From (6.29) we see that the distribution of G depends only on

$$\lambda = \frac{1}{2\sigma^2} \sum_{i=1}^{s} \theta_i^2$$

where $E(y_i) = \theta_i$. Hence we may denote the power of the region (6.44) with respect to the alternative

$$E(y_i) = \theta_i$$
, $(i = 1, \dots, s)$; $E[(y_i - \theta_i)^2] = E[(x_i)^2] = \sigma^2$ by $P_0(\lambda)$.

Let W be another critical region and denote its power function by

$$P(\theta_1, \cdots, \theta_p, \sigma).$$

Consider now in the p-dimensional space z_1 , ..., z_p the surface S defined by

(6.45)
$$2\lambda\sigma^2 = z_1^2 + \cdots + z_s^2, z_i = \theta_i, (i = s + 1, \dots, p)$$

Let $\overline{P}(\lambda, \sigma, \theta_{s+1}, \dots, \theta_{p})$ denote the average power on the surface defined by (6.45). That is to say

$$\overline{P}(\lambda, \sigma, \theta_{s+1}, \cdots, \theta_{p})$$

$$= \left(\int_{S} dA\right)^{-1} \int_{S} P(z_{1}, \dots, z_{s}, \theta_{s+1}, \dots, \theta_{p}, \sigma) dA$$

Wald proved that for all W of the same size as W_0

$$(6.47) \widetilde{P}(\lambda, \sigma, \theta_{s+1}, \cdots, \theta_p) \leq P_0(\lambda).$$

Thus the power of the analysis of variance test is higher than or equal to the mean power over the surface (6.45) of any other test on the same level of significance.

Clearly if $P(\theta_1, \dots, \theta_n, \sigma)$ depends only on λ then $\overline{P}(\lambda) =$ $P(\lambda)$ and it follows from (6.47) that

$$(6.48) P(\lambda) \le P_0(\lambda).$$

The inequality (6.48) had been previously obtained by P. L. Hsu (Biometrika, Jan. 1941).

CHAPTER VII

Latin Squares and Incomplete Balanced Block Designs

Suppose that m varieties of wheat are to be compared as to their mean yield on a certain type of soil. We have at our disposal a rectangular field subdivided into m^2 plots. However, even if we are careful in the selection of our field, differences in soil fertility will occur on it. Thus if all the plots of the first row are occupied by the first variety, it may very well be that the first row is of high fertility and we might obtain a high yield for the first variety although it is not superior to the other varieties. We shall be less likely to vitiate our comparisons, if we replicate every variety once in every row and at the same time randomize the position of the varieties within the rows. We might for instance take m cards with the numbers 1, \cdots , m on them, shuffle them well and then lay them out in a row to determine the position of the varieties in the first row. Repetition of this process will yield the position of the varieties in the second row and so forth. An arrangement of this type is called a randomized block arrangement. A mathematically rigorous treatment of this arrangement is at present not yet available. An approximate test of varietal effects is possible by treating the arrangement as a two-way classification design ignoring the variation of soil fertility within the rows. We shall discuss this design in detail in Chapter XII. A better plan will be the systematic elimination of soil fertility differences, which is preferable to randomization and should be applied whenever it is possible. It yields in most cases more efficient estimates of the varietal effects and has the grea advantage that a mathematically rigorous treatment is avail able.

The line of attack in our particular example is as follows. We conceive of the mean yield $E(y_{ijk})$ of the kth variety of the plot in the *i*th row and *j*th column of the field as given by

(7.1)
$$E(y_{ijk}) = \mu_i + \nu_j + \rho_k + \rho, \\ \sum_i \mu_i = \sum_j \nu_j = \sum_k \rho_k = 0.$$

This assumption is for instance always satisfied if the soil fertility is a linear function of the coordinates, an assumption which is likely to be true if the field is not too large and is homogeneous in appearance. The quantities μ_i , ν_i , ρ_k are called the row, column, and varietal effects respectively. The design is called a Latin square if every variety is planted once in every row and once in every column. The expected value of the mean yield of the kth variety in our experiment is then by (7.1) equal to

$$\frac{1}{m} \sum_{i,j} E(y_{ij}) db = u \mu b rary.org.in$$

where the summation runs over all pairs i, j for which y_{ijk} is defined. Thus

$$y_{\cdot \cdot \cdot k} = \frac{1}{m} \sum_{i,j} y_{ijk}$$

provides an unbiased estimate of $\rho_k + \rho$. Since every variety occurs once in every row and once in every column, the mean y of all yields provides an estimate of ρ so that the varietal effects ρ_k , $(k = 1, \dots, m)$ can be estimated.

The assumption of our linear hypothesis is therefore that the y_{ijk} are normally and independently distributed all with the same but unknown variance σ^2 and that their expectations are given by (7.1). Note that as soon as i and j are fixed k is determined by our design. The parameters $\mu_{ijk} = E(y_{ijk})$ are expressed by the 3m + 1 parameters ν_i , μ_i , ρ_k , $(i, j, k = 1, \dots, m)$ and ρ . However, these parameters are not independent since

$$\sum_{i} \mu_{i} = \sum_{i} \nu_{i} = \sum_{k} \rho_{k} = 0.$$

Hence there are 3m-2 independent parameters and Q_a will therefore have m^2-3m+2 degrees of freedom. The hypotheses

to be tested are manifold. In the first place, we might wish to test whether the varieties differ at all from each other, we shall then test the hypothesis $\rho_i = 0$ $(i = 1, \dots, m)$. Or we may wish to test the difference between two varieties, say ρ_i and ho_2 . The hypothesis to be tested is then $ho_1 =
ho_2$. Also we might wish to test whether the rows (or columns) have any effect. We then test the hypothesis $\mu_i = 0$ (or $\nu_i = 0$), $(i = 1, \dots, m)$ and so forth. We shall first derive Q_a . The design obviously satisfies the conditions of Theorem 4.4 with respect to each of the three sets of variables μ_i , ν_i , ρ_k . Hence in finding Q_a we may by virtue of theorem 4.4 ignore the restrictions in (7.1). Minimizing

$$Q = \sum_{i} \sum_{i} (y_{ijk} - \mu_i - \nu_i - \rho_k - \rho)$$

 $Q = \sum_{i} \sum_{j} (y_{ijk} - \mu_i - \nu_j - \rho_k - \rho)^2$ with respect to μ_i , ν_i , ρ_k , ρ and denoting our estimates of these quantities by $\hat{\mu}_i$, $\hat{\nu}_i$, \hat these quantities by $\hat{\mu}_i$, $\hat{\nu}_i$, $\hat{\rho}_k$, $\hat{\rho}$ we obtain

these quantities by
$$\hat{\mu}_i$$
, $\hat{\nu}_i$, $\hat{\rho}_k$, $\hat{\rho}$ we obtain
$$\hat{\rho} = \frac{1}{m^2} \sum_i \sum_j y_{ijk} = y,$$

$$\hat{\mu}_i = \frac{1}{m} \sum_{i,k} y_{ijk} - y = y_{i..} - y,$$

$$\hat{\nu}_i = \frac{1}{m} \sum_{i,k} y_{ijk} - y = y_{.j.} - y,$$

$$\hat{\rho}_k = \frac{1}{m} \sum_{i,k} y_{ijk} - y = y_{.j.} - y.$$

Because for instance the ith row contains every variety and every column exactly once so that the varietal and the column effects will cancel out. Thus

(7.3)
$$Q_{\bullet} = \sum_{i} \sum_{j} (y_{i,i} - y_{i,..} - y_{.j} - y_{..k} + 2y)^{2}.$$

We now apply theorem 4.2 taking H_1 equal to the assumption,

$$H_2: \mu_i = 0 \ (i = 1, \cdots, m),$$

$$H_3: \quad \nu_j = 0 \ (j = 1, \cdots, m),$$

$$H_4: \rho_k = 0 \ (k = 1, \dots, m).$$

Then

on
$$\sum y_{iik}^2 = \sum (y_{iik} - y_{i..} - y_{.i} - y_{.ik} + 2y)^2 + m \sum (y_{i..} - y)^2 + m \sum (y_{.i} - y)^2 + m \sum (y_{.ik} - y)^2 + m^2y^2.$$
The same decomposition is also obtained, however, if we realise the hypotheses H_2 , H_3 , H_4 . Thus the hypothesis

The same decomposition is also obtained, however, if we renumber the hypotheses H_2 , H_3 , H_4 . Thus the hypothesis $H_4: \rho_k = 0$ is to be tested by dbraulibrary.org.in

$$F = \frac{m^2 - 3m + 2}{m - 1}$$

(7.4)

$$. \frac{m \sum y^{2}_{\cdot \cdot k} - m^{2}y^{2}}{\sum_{i} \sum_{j} y^{2}_{ijk} - m[\sum_{i} y^{2}_{i} + \sum_{i} y^{2}_{\cdot i} + \sum_{k} y^{2}_{\cdot \cdot k}] + 2m^{2}y^{2}}.$$

The expressions for testing row and column effects are entirely analogous. To test the hypothesis $\rho_1 = \rho_2$ we apply formula (4.64). We have $\hat{\rho}_1 - \hat{\rho}_2 = y_{...1} - y_{...2}$. Now $y_{...1}$ and $y_{...2}$ are independent quantities each a mean of m independent observations, thus

$$\sigma_{y...}^2 = \sigma_{y...}^2 = \frac{\sigma^2}{m}$$

and therefore

$$\sigma^2_{(y...-y...)} = \frac{2\sigma^2}{m}.$$

Hence to test $H: \rho_1 = \rho_2$ we have to use

(7.5)
$$F = \frac{m^2 - 3m + 2}{1} \cdot \frac{m(y_{..1} - y_{..2})^2}{2Q_a}.$$

Similarly if we test $H: p_1 = 0$ we have first to compute the variance of $\hat{\rho}_1 = y_{...} - y$. We have

$$\begin{split} \sigma_{(\nu_{-1}-\nu)}^2 &= \sigma_{\nu_{-1}}^2 + 2\sigma_{\nu_{-1}\nu} + \sigma_{\nu}^2 \\ &= \sigma^2 \left(\frac{1}{m} - \frac{2}{m^2} + \frac{1}{m^2}\right) = \frac{\sigma^2}{m} \cdot \frac{m_{-1}-1}{m} \; . \end{split}$$

(7.6)
$$F = \frac{m^3 - 3m + 2}{1} \cdot \frac{m^2}{m - 1} \cdot \frac{(y_{...1} - y)}{Q_a}$$

(7.6) $F = \frac{m^3 - 3m + 2}{1} \cdot \frac{m^2}{m - 1} \cdot \frac{(y_{-1} - y)^2}{Q_a}$ is the likelihood ratio statistic for testing $H: \rho_1 = 0$.

The treatment of experiments set out in the interpolations each of the property of the p replications each of which constitutes a Latin square does not offer any particular difficulty. The observations may be denoted by $y_{ijk}^{(l)}$ where l is the replication number. The assumption states

(7.7)
$$\frac{\sqrt{E}(y_{ijk}^{\text{disprachimeary.org.in}} + \rho_k + \alpha_{(1)} + \mu,}{\sum_{i} \mu_i^{(1)} = \sum_{i} \nu_i^{(1)} = \sum_{k} \rho_k = \sum_{i} \alpha_{(1)} = 0.}$$

The number of independent parameters is

$$r(m-1)$$
 for row effects,
 $r(m-1)$ for column effects,
 $(m-1)$ for varietal effects,
 $(r-1)$ for replicates,
1 for mean.

Hence the number of degrees of freedom for Q_a becomes (m-1)

It is often possible to test at the same time other effects of the yield, for instance we might be able to apply m differen fertilizers and to construct a design which forms a Latin squar with respect to fertilizers and varieties each and has in addition to this the property that every fertilizer is applied exactly one to every variety. For m = 4 one could use for instance the design

$$egin{array}{llll} v_1f_1 & v_2f_2 & v_3f_3 & v_4f_4 \\ v_2f_3 & v_1f_4 & v_4f_1 & v_3f_2 \\ v_3f_4 & v_4f_3 & v_1f_2 & v_2f_1 \\ v_4f_2 & v_3f_1 & v_2f_4 & v_1f_3 \end{array}$$

where v_1 , v_2 , v_3 , v_4 denote the 4 varieties, f_1 , f_2 , f_3 , f_4 denote the 4 fertilizers.

This idea can be generalized to test the effects of r different categories of conditions for each of which there are m possibilities. We then need designs with the following properties. There are r different letters. Each of these letters occurs m times with each of the indices $1, \dots, m$. They are to be arranged into a square, divided dintaring asybequares, in such a way that the indices on each letter form a Latin square and so that each pair of letters occurs with each pair of indices exactly once in one of the subsquares. A design of this type is called a set of r orthogonal Latin squares.

The analysis of these designs is entirely analogous to that of the Latin square design. The required F statistics can easily be obtained by applying Theorem 4.1.

If the assumptions made for the analysis of the Latin square are justified then the Latin square is the best design for field experiments, which is at present available. However, it is necessary in a Latin square that the number of experiments on each variety be equal to the total number of varieties investigated. Thus if the number of varieties is large the number of replications becomes likewise large. This means not only an unduly large expense for the experiment but also necessitates the use of large blocks, so that the assumption (7.1) which underlies the analysis of the Latin square is not even approximately fulfilled. We shall therefore discuss other designs which take care of this situation.

If we plant the varieties in relatively small blocks we may assume that the soil fertility is the same for each plot in the same block.

Thus again making the assumption that the mean yield is a linear function of varietal effect and block effect we have

(7.8)
$$E(y_{ij}) = v_i + b_j + \mu, \qquad \sum_i v_i = \sum_j b_j = 0,$$

where y_{ij} is the yield of the experiment which consists in planting the ith variety on a plot of the jth block. Applying the likelihood ratio principle to the linear hypothesis (7.8) we have

(7.9)
$$Q = \sum_{i,i} (y_{ii} - v_i - b_i - \mu)^2,$$

where $\sum_{i,j}$ runs over all pairs i,j for which the *i*th variety occurs in the jth block, with respect to v_i , b_i and μ under the restriction $\sum_{i}^{i} v_{i} = \sum_{i}^{i} b_{i} = 0$. Minimizing Q and denoting least square estimates by carets leads to the equations

(7.10)
$$V_{i} = \sum_{i} r_{i} \hat{\theta}_{i} + \sum_{j} k_{j} \hat{b}_{j} + N\hat{\mu},$$

$$V_{i} = r_{i} \hat{\theta}_{i} + \sum_{(i)} \hat{b}_{i} + r_{i} \hat{\mu},$$

$$B_{i} = \sum_{(i)} \hat{\theta}_{i} + k_{i} \hat{b}_{j} + k_{j} \hat{\mu}$$
Since by Theorem

since by Theorem 4.4 the restrictions $\sum v_i = \sum b_i = 0$ may

V, denotes the sum of the yields of the ith variety, B_i denotes the sum of the yields in the jth block, r_i denotes the number of replicates of the ith variety, $\underline{k_i}$ denotes the number of plots in the jth block, $\sum_{i,j} b_i$ denotes the sum of the effects of all blocks, which contain a plot with the ith variety. v. denotes the sum of the varietal effects of all varieties

that occur in the jth block. N is the number of experiments.

In order that such a design be really useful, the following requirements must be fulfilled:

1.) The solution to the system 7.10 must exist and must be unique.

- 2.) It must be possible to compute the solutions to 7.10 within a reasonable time.
- 3.) The estimates of the varietal effects should be reasonably accurate.

The \hat{v}_i and \hat{b}_j are linear functions of the observations. Hence if the y_{ij} are normally distributed, then each \hat{v}_i , \hat{b}_j , $\hat{\mu}$ will be normally distributed.

The size of the resulting confidence interval for v_i is then exactly proportional to its standard deviation. The requirement 3 is somewhat vague. Suppose every variety occurs the same number of times and it would be possible to carry out an experiment in a two by two classification according to blocks and varieties with a complete replication in every block. In such a design the estimate θ_i would then have a certain variance σ^2/h . Suppose the variance of v_i as computed from (7.10) is σ^2/c_i . Then

$$(7.11) e = \frac{c_i}{h}$$

is called the efficiency factor of the design leading to (7.10) with respect to the estimate θ_i . The efficiency factors with respect to varietal differences are defined similarly. Clearly if there is a choice between two designs one of which is more efficient than the other whilst both justify the assumption 7.8, then the experimenter will choose the more efficient design.

Various designs have been constructed which satisfy the requirements 1 and 2 and the requirement 3 to a fairly satisfactory extent. The best of these are the incomplete balanced block designs. These are available for certain combinations of the number of varieties and number of replications.

A balanced block design is an arrangement of v varieties into b blocks of k plots each such that

- No block contains the same variety twice.
- 2.) Every variety is replicated r times.
- 3.) Every variety v_i occurs with every other variety v_i exactly λ times together in the same block.

The total number of experiments is bk on the one hand and rv on the other hand so that

$$(7.12) b \cdot k = r \cdot v.$$

Every variety v_i occurs in r blocks. These r blocks contain r(k-1) varieties different from v_i . Since every $v_i \neq v_i$ occurs among them exactly \(\lambda\) times

(7.13)
$$r(k-1) = \lambda(v-1).$$

Equations 12 and 13 are necessary conditions for the existence of a block with the parameters b, v, r, k, λ . Another necessary condition for a design in which not every variety is repeated in every block is

(7.14)

.14) $b \ge v$.

The condition (7.14) was first proved by R. A. Fisher, Ann. of Eugenics (1940) 10 pp. 52-75, and will be derived later. The conditions (7.12), (7.13) and (7.14) are not sufficient for the existence of the design. Thus for instance the design v = b = 43, r = k = 7, $\lambda = 1$ is known to be impossible. In fact necessary and sufficient conditions are at the present time not yet known Various methods for the construction of incomplete balanced block designs will be given in the next chapter.

We proceed to discuss the analysis of balanced incomplete block designs and note first that in 7.10 $r_i = r$, $k_i = k$. Hence on account of $\sum_{i} v_{i} = \sum_{i} b_{i} = 0$ 7.10 reduces to

$$\sum_{i,j} y_{ij} = rv\hat{\mu},$$

(7.15)
$$V_{i} = r\theta_{i} + \sum_{(i)} \hat{b}_{i} + r\hat{\mu},$$
$$B_{i} = \sum_{(i)} \theta_{i} + k\hat{h}_{i} + k\hat{\mu}.$$

We put $T_i = \sum_{(i)} B_i = \text{sum of the totals of all the block}$ which contain the ith variety. Summing the third equation is (7.15) over all blocks containing the ith variety we obtain

(7.16)
$$T_i = k \sum_{(i)} \hat{b}_i + (r - \lambda)\hat{v}_i + rk\hat{\mu}$$

#

since $\sum_{i} \hat{v}_{i} = 0$ and since every variety different from v_{i} occurs in the sum λ times whilst v_i occurs r times. Multiplying the second of the equations (7.15) by k we obtain

(7.17)
$$kV_{i} = k \sum_{(i)} \hat{b}_{i} + rk\hat{v}_{i} + rk\hat{\mu}.$$

Subtracting (7.16) from (7.17) we get

$$(7.18) (rk - r + \lambda)\hat{v}_i = kV_i - T_i.$$

Substituting from (7.12) and (7.13)

$$rk - r + \lambda = r(k - 1) + \lambda = \lambda(v - 1) + \lambda = \lambda v.$$

Hence

$$\hat{\mu} = y$$
,

Substituting (7.16) from (7.17) we get
$$(7.18) \qquad (rk - r + \lambda)\hat{v}_i = kV_i - T_i .$$
 Substituting from (7.12) and (7.13)
$$rk - r + \lambda = r(k-1) + \lambda = \lambda(v-1) + \lambda = \lambda v.$$
 Hence
$$\hat{\mu} = y,$$
 (7.19)
$$\hat{v}_i = \frac{1}{\lambda v} \left(kV_i - T_i \right)_{\text{www.dbreulibrary.org.in}}$$

$$\hat{b}_i = \frac{1}{k} B_i - \frac{1}{\lambda k v} \sum_{i=1}^{(i)} \left(kV_i - T_i \right) - y.$$

We observe that $(k-1)V_i$ and $T_i - V_i$ are independent quantities and therefore

(7.20)
$$\frac{\sigma_{6i}^2}{\sigma^2} = \frac{1}{\lambda^2 v^2} \left[(k-1)^2 r + r(k-1) \right] \\ = \frac{rk(k-1)}{\lambda^2 v^2} = \frac{k(v-1)}{\lambda v^2} .$$

We now apply Theorem 4.2 to the sequence of hypotheses

$$H_1: E(y_{ij}) = v_i + b_i + \mu, \quad H_2: \quad v_i = 0 \ (i = 1, \dots, v),$$

$$H_3: \quad b_i = 0 \ (j = 1, \dots b).$$

Then

$$Q_{u} = \sum_{i,j} y_{ij}^{2} - \frac{1}{k} \sum_{i} B_{i}^{2} - \sum_{i,j} \left(\hat{v}_{i} - \frac{1}{k} \sum_{i}^{(j)} v_{i} \right)^{2},$$

(7.21)

$$Q_r = \sum_{i,j} y_{ij}^2 - \frac{1}{k} \sum_{i} B_i^2 .$$

On account of the conditions of an incomplete block design the expression for $Q_r = Q_a$ is symmetric in the r_i , $(i = 1, \dots, v)$. Hence by Theorem 4.5 and on account of 7.20

$$Q_r - Q_a = \frac{\lambda v}{k} \sum_i \hat{v}_i^2 ,$$

(7.22)

$$Q_{\star} = \sum_{i,j} y_{ij}^2 - \frac{1}{k} \sum_i B_i^2 - \frac{\lambda v}{k} \sum_i \beta_i^2 \ . \label{eq:Qs}$$

To carry out tests of significance for the hypothesis $v_i = v_i$ it is necessary to know the variance of $\hat{v}_i = \hat{v}_i$. We have

(7.23)
$$\sigma_{i_i-i_j}^2 = \sigma_{i_j}^2 + \sigma_{i_{i,s}}^2 - 2\sigma_{i_{i,j}}.$$

Now θ_i and θ_i are given by (7.19). Counting the observations common to the terms in (7.19), we find no common observation in V_i and V_{ij} are well as in V_{ij} . Thus

$$\lambda^2 v^2 \sigma_{ijij} = (-k\lambda - k\lambda + k\lambda)\sigma^2 = -k\lambda\sigma^2$$

and therefore

(7.24)
$$\frac{\sigma_{s_v-6_v}^2}{\sigma^2} = \frac{2k(v-1)}{\lambda v^2} + \frac{2k}{\lambda v^2} = \frac{2k}{\lambda v} .$$

Application of the corollary to Theorem 4.3 then yields the proper test statistic for testing the hypothesis $v_i = v_i$.

To find the efficiency factors with respect to \hat{v}_i and $\hat{v}_i - \hat{v}_i$ we have to compute the variance of the estimates \hat{v}_i , $\hat{v}_i - \hat{v}_i$ in a two-way classification design with r replications and these are easily found to be v - 1/rv and 2/r respectively so that in both cases the efficiency factor is $\lambda v/rk$. This is mostly quite satisfactory, as for instance in the designs

$$(v, b, r, k, \lambda) = (16, 24, 9, 6, 3), (8, 14, 7, 4, 3),$$

 $(11, 11, 5, 5, 2)$ or $(21, 21, 5, 5, 1).$

CHAPTER VIII

Galois Fields and Orthogonal Latin Squares

IT WAS SEEN IN CHAPTER VII that the analysis of sets of orthogonal Latin squares and of incomplete balanced block designs offers no particular difficulty. The construction of these designs however leads to very interesting combinatorial problems, some of which are not yet completely solved.

A Latin square of side m is an arrangement of m letters into m^2 subsquares of a square in such a way that every row and every column contains every letter exactly once. Two Latin squares are termed orthogonal if, when one is superimposed upon the other, every ordered pair of symbols occurs exactly once in the resulting square. Thus the Latin squares

are orthogonal. The problem of constructing, for instance, a set of r orthogonal Latin squares of side m could be regarded as solved if we either can give a method by which such a design can be constructed or are able to prove that the design cannot exist. This problem is at present still unsolved for many combinations of r and m. Various methods have been discovered however for obtaining solutions in a great many cases. In fact, within the range useful in the design of experiments, the solution has been obtained for most cases with only a few exceptions. The experimenter will usually not go beyond m = 13. The problem of the construction of orthogonal Latin squares within this range is solved for m = 2, 3, 4, 5, 6, 7, 8, 9, 11, 13. That is to say, (m - 1) orthogonal Latin squares of side m can be constructed for m = 2, 3, 4, 5, 7, 8, 9, 11, 13 while it is proved that no six-sided orthogonal pair exists nor more

than (m-1) orthogonal Latin squares of side m. An orthogonal pair of side 12 can be constructed, but it is not known whether a pair of orthogonal 10 sided squares or a triple of orthogonal 12 sided squares exists.

To understand the methods by which orthogonal Latinguages have been constructed we need certain elementary concepts of algebra and of the theory of numbers which will be developed presently.

Let a, b, m be integers. We shall write

$$a \equiv b(m)$$

in words, a congruent to b modulo m, if m divides a-b. Such congruences can be treated like equations. For instance if $a \equiv b(m)$, then $a \pm c \equiv b \pm c(m)$, $ac \equiv bc(m)$. The proof of these two propositions is left to the reader. If also $c \equiv d(m)$, then $ac \cong bd(m)$, $ac \equiv b \pm d(m)$.

Proof: According to our definition we have

$$a-b=\lambda_1 m$$
, $c-d=\lambda_2 m$, λ_1 , λ_2 integers.

Hence $ac = bd + m(\lambda_2 b + \lambda_1 d) + \lambda_1 \lambda_2 m^2$ and therefore

$$(8.2) ac \equiv bd(m).$$

The relation $a \pm c \equiv b \pm d(m)$ follows in a similar manner.

The rules for division of congruences are not so simple. We shall prove however the following rule:

If $ac \equiv bc(m)$ and t = (m, c) is the greatest common divis (g.c.d.) of m and c then

$$(8.3) a = b\left(\frac{m}{t}\right).$$

Proof: $ac - bc = \lambda m$, λ integral. Hence

$$(8.4) a - b = \frac{\lambda m}{c} = \frac{\lambda}{c/t} \cdot \frac{m}{t}.$$

The left side of (8.4) is an integer. Since m/t and c/t are integand c/t is prime to m/t, it follows that λ is divisible by

Hence $\lambda/(c/t)$ is an integer and m/t divides a-b. In particular it follows that we may divide a congruence by any number (which is prime to the modulus. If m is a prime number p then we may divide congruences mod p by any number a such that $a \not\equiv 0(p)$.

. In the following we shall always calculate mod p. That is to say, we shall replace every number by its smallest positive residue mod p. For instance $4+2\equiv 1(5)$, $2.8\equiv 1(5)$ and so forth.

Let p be a prime number and form the following design.

All numbers in L_i are reduced mod p. We shall show that L_i is a Latin square. If this were not true, then since only the symbols $0, 1, \dots, p-1$ occur in L_i , we would have some row or column in which one of the symbols occurs twice. If the ith row contains the same number in the kth column and in the rth column we should have

$$k + ij \equiv r + ij(p),$$

$$k \equiv r(p).$$

A similar argument shows that every column contains every number exactly once. Thus L_i , $(j=1,\cdots,p-1)$ is a Latin square. We shall show now that L_i is orthogonal to L_i if $i\neq j$. If this were not the case, we should have the same ordered pair of numbers occurring in two different boxes of the square which results from superimposition of L_i on L_i . Let mn be a

pair which occurs twice and assume that it occurs in the α th row and β th column and in the γ th row and δ th column. Then

$$\beta + \alpha j \equiv \delta + \gamma j \equiv m(p),$$

 $\beta + \alpha i \equiv \delta + \gamma i \equiv n(p).$

Hence

$$\alpha(i-j) \equiv \gamma(i-j)(p).$$

But -p < (i - j) < p and (i - j) is therefore prime to p. We may therefore divide by i - j and obtain $\alpha \equiv \gamma(p)$,

As an example we present a set of 4 orthogonal 5 sided squares.

I. ·	
$\stackrel{L_1}{ ext{www.dbraulib}}$ ery.org.in L_3	L_{4}
$\begin{smallmatrix}0&1&2&3&4\\&&&&&0&1&2&3&4\\&&&&&&&0&1&2&3&4\end{smallmatrix}$	0 1 2 3 4

If we consider the properties of the system of residues mod p which were used in constructing the L_i we note that, particularly, the uniqueness of the division was necessary. Because of the uniqueness of the division the residues $a, 2a, \dots, (p-1)a$ are (p-1) different residues all different from 0 provided $a \neq 0(p)$. Hence one of them must be the residue 1. Thus to

every residue $a \not\equiv 0(p)$ there exists a residue a^{-1} called the inverse of a such that $a \cdot a^{-1} \equiv 1(p)$.

From our method of constructing m-1 orthogonal squares if m is a prime number, it may be surmised that we can always construct m-1 orthogonal Latin squares if we have a system.

To every pair of elements a, b in \mathfrak{F} there exist two uniquely determined elements a+b and $a \cdot b$ in \mathfrak{F} . The "addition" and "multiplication" satisfy the following conditions:

I.
$$a + b = b + a$$
, $ab = ba$, The commutative law.

II.
$$(a + b) + c = a + (b + c)$$
, $(ab)c = a(bc)$, The associative law.

III. There exist two elements 0, 1 in & such that

$$a+0=a$$
 $a\cdot 1=a$

for every a in F.

IV. To every $a \neq 0$ there exists an element (-a) and an element a^{-1} such that

www.dbraulibrary.org.in
$$a + (-a) = 0$$
, $a \cdot a^{-1} = 1$.

The element a^{-1} is called the inverse of a.

V.
$$c(a + b) = ca + cb$$
. The distributive law.

A system satisfying the postulates I - V is called a field. If the number of elements, which we shall call the marks of the field, is finite, then it is called a finite field or a Galois field. It may be remarked that the commutative law of addition, and, if the field is finite, also the commutative law of multiplication need not be postulated.

Let $g_0 = 0$, $g_1 = 1$, g_2 , \cdots , g_{m-1} be the elements of the finite field \mathfrak{F} and form the designs:

 $\hat{N}_{\hat{z}_n}$

Then by exactly the same argument that was applied in the case of the field of residues mod m we can show that L_1, \dots, L_{m-1} is a set of m-1 orthogonal Latin squares. Hence we have

THEOREM 8.1: If $g_0 = 0$, $g_1 = 1$, g_2 , \cdots , g_{m-1} are the marks of a finite field, then the designs L_i of (8.6) form a set of m-1 orthogonal Latin squares.

In a field & the following propositions hold:

Proposition 1: $a \cdot 0 = 0$ for every a.

Proof: $a = a(1 + 0) = a + a \cdot 0$; adding (-a) to both sides of this equation we obtain Proposition 1.

Proposition 2: ab = 0, $a \neq \hat{0}$ implies b = 0.

Proof: This follows by multiplying ab = 0 with a^{-1} .

We denote by $m_{a}m_{1}$ where orgin an integer and x a mark of x the sum of mx's. We then have

. Proposition 3: If m is an integer such that $m \cdot 1 = 0$ then $m \cdot x = 0$ for every x. If mx = 0 for one $x \neq 0$, then my = 0 for all y in \mathfrak{F} .

Proof: If $m \cdot 1 = 0$ then $mx = (m \cdot 1)x = 0x = 0$. Also if mx = 0 then $mx = (m \cdot 1)x = 0$ if $x \neq 0$ then by Proposition $1 \cdot m \cdot 1 = 0$ and therefore $m \cdot y = 0$ for every y.

• Proposition 4: Let p be the smallest positive integer for which $p \cdot 1 = 0$ then p is a prime. (Such an integer need, of course not exist.)

Proof: Suppose p = mn, m < p, n < p then $mn \cdot 1 = (m \cdot 1)(n \cdot 1) = 0$. Hence either $m \cdot 1 = 0$ or $n \cdot 1 = 0$ controllecting the significance of p.

The number p is called the characteristic of the field. If there is no integer p for which $p \cdot 1 = 0$ then the field is called a field of characteristic 0 and is necessarily infinite because the elements $n \cdot 1$, n = 0, $1, \dots$ ad. inf. are then all different.

THEOREM 8.2: The number of elements in a Galois field F is power of its characteristic v.

Proof: Put $w_1 = 1$. If there is a mark $w_2 \neq a \cdot 1$ for $a = \cdots$, p = 1 form all marks $a_1w_1 + a_2w_2$, $a_1 = 0, 1, \cdots, p = 1$

 $a_2 = 0, 1, \dots, p-1$. These are p^2 different marks. If they do not yet exhaust all the marks of \mathfrak{F} then take a mark w_3 different from $a_1w_1 + a_2w_2$ and form all marks $a_1w_1 + a_2w_2 + a_3w_3$. Continue the process until all marks of \mathfrak{F} are exhausted. If w_1, \dots, w_m are obtained in this way, then $a_1w_1 + \dots + a_mw_m$ $(a_i = 0, 1, \dots, p-1)$ represent all the marks of \mathfrak{F} . If

$$(8.7) a_1 w_1 + \cdots + a_m w_m = b_1 w_1 + \cdots + b_m w_m$$

then $(a_1 - b_1)w_1 + \cdots + (a_m - b_m)w_m = 0$. Let k be the largest number for which $a_k - b_k = -c_k \neq 0$. Then

$$c_k w_k = (a_1 - b_1)w_1 + \cdots + (a_{k-1} - b_{k-1})w_{k-1}$$

Let c_k^{-1} be the inverse to c_k in the field of residues mod p then

$$\begin{array}{lll} w_{k} = c_{k}^{-1}(a_{1} - b_{1})w_{1} + \cdots + c_{k}^{-1}(a_{k-1} - b_{k-1})w_{k-1} \\ & & \text{www.dbraulibrary.org.in} \\ = d_{1}w_{1} + \cdots + d_{k-1}w_{k-1} \end{array}$$

where d_1 , \cdots , d_{k-1} are residues mod p. But this contradicts the significance of w_k . Hence \mathfrak{F} contains p^m elements.

Let α be any mark of a Galois field, G.F. (p^m) , and form $1, \alpha, \alpha^2, \dots, \alpha^k, \dots$. Since the number of marks is finite we must have for some k > j

$$\alpha^k = \alpha^i, \qquad \alpha^{k-i} = 1.$$

Definition: If t is the smallest positive integer such that $\alpha^t = 1$, then t is called the order of α .

Let x_1, \dots, x_{p^m-1} , be all the non-zero elements of G.F. (p^m) then

$$\alpha x_1 \alpha x_2 \cdots \alpha x_{p^m-1} = x_1 \cdots x_{p^m-1}$$
 if $\alpha \neq 0$.

Hence

(8.8)
$$\alpha^{p^{m-1}} = 1 \quad \text{for all } \alpha \neq 0.$$

We shall prove now several propositions on the order of elements of a finite field \Re .

Proposition 5: If s is the order of α and $\alpha^n = 1$, then $n \equiv 0(s)$. For we can find an integer λ such that $n = \lambda s + r$, $0 \le r < s$, and $\alpha^n = 1$ implies $\alpha^r = 1$, hence r = 0, since s is the order of α . Corollary: If s is the order of α then $p^m - 1 \approx 0(s)$.

Proposition 6: If α has the order s and β the order t and (s, t) = 1, then $\alpha \cdot \beta$ has the order st.

Proof: $(\alpha\beta)' = 1$ implies $\beta^{rr} = 1$ and $sr \equiv 0(t)$ by Proposition 5. Hence $r \equiv 0(t)$ and similarly $r \equiv 0(s)$. Thus $r \equiv 0(st)$. But

b. Hence r = U(t) and similarly r = U(s). Thus r = U(st). $(\alpha \beta)^{**} = 1$ and st is therefore the order of $\alpha \cdot \beta$.

Proposition 7: If α has the order $\lambda \mu$ then α^{λ} has the order μ . The proof is left to the reader.

Proposition 8: If s is the largest order occurring in a Galais field \mathfrak{F} and if t is any order then $s \equiv 0(t)$.

Proof: If $s \neq 0(t)$ then for some prime p we should have s = p'r, t = p'r', (p, r) = (p, r') = 1, f > e. If α has the order s and β the order t, then by propositions 6 and 7 $\alpha^p \beta^{r'}$ has the order $p' \cdot r > s$, but this contradicts the significance of s.

Definition: A mark of order $p^m - 1$ in the Galois field of order p^m is called a problem of the problem of the control of

THEOREM 8.3: A Galois field G.F. (p^m) of order p^m , has $\phi(p^m-1)$ primitive roots, where $\phi(n)$ denotes the number of residues mod n which are prime to n.

Lemma 8.1: A polynomial $P(x) = x^n + a_1 x^{n-1} + \cdots + a_n$ of degree n with coefficients in G.F. (p^m) has at most n roots.

Let α be a root of P(x). Then $P(\alpha) = 0$. Hence

$$P(x) = P(x) - P(\alpha)$$

$$= x^n - \alpha^n + \dots + a_{n-1}(x - \alpha) = (x - \alpha)Q(x)$$

where Q(x) is a polynomial of degree (n-1) with coefficients in G.F. (p^m) . If β is a root of P(x), then by Proposition 2 either $\beta = \alpha$ or $Q(\beta) = 0$. Lemma 8.1 then follows easily by induction.

Proof of Theorem 8.3: Let s be the largest order occurring in $G.F.(p^m)$. Then since every order divides s we must have for every α in $G.F.(p^m)$

$$\alpha' = 1.$$

By lemma 8.1 it follows from (8.11) that $s \ge p^m - 1$ but also $p^m - 1 \equiv 0(s)$ and therefore $p^m - 1 = s$. Thus there exists at least one primitive root. Let w be this primitive root,

then w^i where i is prime to $p^m - 1$ is also a primitive root. Hence there are $\phi(p^m - 1)$ primitive roots.

If a primitive root is known then the construction of a set of (m-1) orthogonal Latin squares can be simplified considerably. Let w be a primitive root and $0, 1, x_3, \dots, x_n$ be the elements of a finite field of order n then

are n-1 orthogonal Latin squares. It should be observed that \overline{L}_{i+1} is obtained from \overline{L}_i by cyclically permuting the last n-1 rows.

We now proceed to construct a G.F. (p^m) for every m and every p. If m = 1 then the residues mod p form a G.F.(p).

We consider polynomials

$$p(x) = x^n + a_1 x^{n-1} + \cdots + a_n$$

whose coefficients a_1 , \cdots , a_n are elements of a field. We shall prove:

THEOREM 8.4: If p(x), q(x) are polynomials with coefficients in a field \mathfrak{F} then there exists a polynomial d(x) such that

(8.13)
$$p(x) \equiv 0(d(x)), \quad q(x) \equiv 0(d(x))$$

and such that $p(x) \equiv 0(h(x))$, $q(x) \equiv 0(h(x))$ implies $d(x) \equiv 0(h(x))$. Further there exist polynomials a(x) and b(x) such that

(8.14)
$$a(x)p(x) + b(x)q(x) = d(x).$$

If d(x) has the first coefficient 1 then d(x) is called the greatest common divisor of p(x) and q(x) and we shall write

$$(8.15) (p(x), q(x)) = d(x).$$

If d(x) fulfills the conditions of Theorem 8.4 then $a \cdot d(x)$ also fulfills these conditions for every non-zero mark a of \mathfrak{F} . Hence if b is the first coefficient of d(x) then $b^{-1}d(x)$ also fulfills the conditions of Theorem 8.4 and has first coefficient 1. It also follows that the greatest common divisor is uniquely determined.

Proof of Theorem 8.4: Consider all expressions of the form

(8.16)
$$a(x)p(x) + b(x)q(x) = d(x)$$

for all a(x) and b(x). Let d(x) in 8.16 have the lowest possible degree whereby the polynomial 0 is not considered to have a degree. We shall prove that d(x) satisfies the conditions of Theorem 8.4. By long division we can obtain a polynomial h(x) such that

is either 0 or has a smaller degree than d(x). Multiplying 8.16 by h(x) we have

$$h(x)a(x)p(x) + h(x)b(x)q(x) = p(x) - r(x)$$

Putting

$$\vec{a}(x) = -[h(x)a(x) - 1], \quad \vec{b}(x) = -[h(x)b(x)]$$

we have

$$\overline{a}(x)p(x) + \overline{b}(x)q(x) = r(x).$$

Since d(x) has the lowest degree of all polynomials 8.16 if follows that r(x) = 0. Thus $p(x) \equiv 0(d(x))$. Similarly $q(x) \equiv 0(d(x))$. From 8.16 it is obvious that d(x) also fulfills all the other conditions of Theorem 8.4.

Definition: If g(x) with coefficients in a field F has no divisor except a and $a \cdot g(x)$ with $a \subset F$, then g(x) is called irreducible in F.

We now define congruences modulo a polynomial m(x) is exactly the same way as congruences in the system of all it tegers. We then calculate mod m(x) by adding, subtracting

and multiplying in the ordinary manner and by always replacing every polynomial f(x) by the residue of smallest degree obtained in dividing f(x) by m(x).

THEOREM 8.5: If g(x) is irreducible in \mathfrak{F} then the residues mod g(x) in the system $\mathfrak{F}(x)$ of all polynomials with coefficients in $\mathfrak{F}(x)$ form a field.

That the field postulates are satisfied by the system of residues mod g(x) is obvious except for the existence of an inverse. Hence Theorem 8.5 is proved if we can prove: To every $f(x) \neq 0(g(x))$ there exists a q(x) such that $f(x)q(x) \equiv 1(g(x))$. This is equivalent to stating that there exists a $\lambda(x)$ such that

(8.18)
$$f(x)q(x) - 1 = \lambda(x)g(x).$$

Since g(x) is irreducible and g(x) is g(x) = 0 (g(x)) we have g(x) = 1 and Theorem 8.5 follows from 8.16.

We now take \mathfrak{F} to be the finite field, G.F.(p) of residues mod p, then we have

Corollary to Theorem 8.5: If g(x) of degree n with coefficients in G.F.(p) is irreducible in G.F.(p) then the residues mod g(x) form a Galois field with p^n elements.

Every polynomial with coefficients in G.F.(p) is, mod g(x), congruent to one of the p^* polynomials

$$(8.19) a_0 + a_1 x + \cdots + a_{n-1} x^{n-1},$$

where a_0 , a_1 , \cdots , a_{n-1} may be any of the residues mod p.

Hence to construct a G.F. (p^n) we have to find an irreducible polynomial of degree n with coefficients in G.F. (p).

For instance the polynomial $x^2 + x + 1$ is irreducible mod 2. Hence the residue 0, 1, x, x + 1 form a G.F.(2^2). Also

$$x^{0} \equiv 1(x^{2} + x + 1),$$

 $x^{1} \equiv x(x^{2} + x + 1),$
 $x^{2} \equiv x + 1(x^{2} + x + 1).$

Hence x is a primitive root of this Galois field. Writing the addition and multiplication tables for the marks 0, 1, x, x + 1we have

Addition					
	0	1	x	x + 1	
0	0	1	x	x + 1	
1	1	0	x + 1	x	
x	æ	x + 1	0	SOL	
x + 1	x+1	\boldsymbol{x}	1 3	10	
$\begin{array}{c} \text{Multiplication} \\ \text{www.dbraulibrary.org.in} \\ 1 & x & x+1 \end{array}$					
0	0	May.	0	0	
1	2	1	\boldsymbol{x}	x + 1	
æ s	00	\boldsymbol{x}	x + 1	1	
40 1	0	x + 1	1	\boldsymbol{x}	

From the addition table we obtain, since x is a primitive root, 3 orthogonal Latin squares of side 4 by cyclically permuting the last 3 rows. We shall however replace x by 2 and x + 1 by 3. This yields the following 3 orthogonal Latin squares.

0 1 2 3	0 1 2 3	0123
1032	2301	3 2 1 0
2301	3 2 1 0	1032
320-1	1032	2 3 0 1

The polynomial $x^2 + x - 1$ is irreducible mod 3 since

$$0^{2} + 0 - 1 \equiv -1(3),$$
 $1^{2} + 1 - 1 \equiv 1(3),$
 $(-1)^{2} + (-1) - 1 \equiv (-1)(3).$

The mark x is a primitive root for

$$x^{0} = 1,$$
 $x^{4} = -1,$
 $x^{1} = x,$ $x^{5} = -x,$
 $x^{2} = -x + 1,$ $x^{6} = x - 1,$
 $x^{3} = -x - 1,$ $x^{7} = x + 1.$

We leave it to the reader to obtain, using this Galois field, 8 orthogonal Latin squares of side 9.

THEOREM 8.6: There is a Galois field of order p' to every prime 'p and every r. www.dbraulibrary.org.in

The proof requires several steps.

Lemma 8.2: Every modulo p irreducible polynomial of degree r is, mod p, a divisor of $x^{p^{r-1}} - 1$.

We shall write $a(x) \equiv b(x) \mod (f(x), p)$ (in words a(x) congruent b(x) modulis f(x) and p) if a(x) - b(x) is divisible by $f(x) \mod p$. The residues mod (f(x), p) form a Galois field of order p'. Hence

$$x^{p^{r-1}} \equiv 1(f(x), p),$$

$$x^{p^{r-1}} - 1 \equiv 0(f(x), p)$$

and this is Lemma 8.2.

(8.20)

Lemma 8.3: If f(x) is irreducible mod p and of degree s > r then f(x) is mod p not a divisor of $x^{p^r-1} - 1$.

Assume that $x^{p^*-1} - 1 \equiv 0(f(x), p)$ and consider the Galois field of residues mod (f(x), p). The order of this Galois field is p^* . Every element of this Galois field is of the form $a_0 + a_1x + p^*$. Every element of this Galois field is of the form $a_0 + a_1x + p^*$. $\cdots + a_kx^k$, k < s where a_0 , a_1 , \cdots , a_k are residues mod p. Now

$$(8.21) (a_0 + a_1 x + \cdots + a_k x^k)^{p^k}$$

$$\equiv a_0 + a_1x + \cdots + a_kx^*(f(x), p)$$

since $x^{p'} \equiv x(f(x), p)$ by assumption. Hence p' = 1 is an upper bound for the order in our Galois field, but this contradicts. Theorem 8.3 since s > r.

Lemma 8.4: The polynomial $x^m - 1$ has no double roots mod p if $m \neq 0(p)$.

We can define the differential quotient for polynomials mod p by the same formal rules as in ordinary calculus. It is easy to prove then that a polynomial has, mod p, a double root only if f(x) and df/dx have a common factor. But obviously $x^m - 1$ and mx^{m-1} have, mod p, no factor in common if m is prime to p.

We can now prove Theorems 8:6: The polynomial $x^{p^{r-1}}-1$ has, mod p, who irreducible factor of degree larger than r. All the irreducible polynomials of degree f < r are, mod p, factors of $x^{p^{r-1}}-1$. Since $x^{p^{r-1}}-1$ has no double roots, the sum of the degrees of all irreducible factors of degree f together is thus at most p'-1. Hence the sum of the degrees of all factors of degree f is at most

$$\sum_{j=1}^{r-1} p^j < \frac{p^r-1}{p-1}.$$

Hence there must be at least one irreducible factor of degree rLet f(x) be this polynomial. Then the expressions

$$(8.22) a_0 + a_1 x + \cdots + a_{r-1} x^{r-1}$$

 $\mod(p, f(x))$ form a Galois field of order p'.

Definition: Two fields \mathfrak{F} and \mathfrak{F}' are called isomorphic if there exists a bi-unique correspondence $a \leftrightarrow a'$, $a \subset \mathfrak{F}$, $a' \subset \mathfrak{F}'$ such that $a \leftrightarrow a'$, $b \leftrightarrow b'$ implies $a + b \leftrightarrow a' + b'$, $ab \leftrightarrow a'b'$.

THEOREM 8.7: Any two Galois fields with p' marks are is morphic.

It is easy to see that every G.F.(p) is isomorphic with the system of residues mod p. We know that there exists a mod p irreducible polynomial g(x) of degree r. Let \mathfrak{F} be any Galois field with p' marks $\alpha_0 = 0$, $\alpha_1 = 1$, α_2 , \cdots , $\alpha_{p'-1}$. Then $x^{p'-1} - 1 = (x - \alpha_1) \cdots (x - \alpha_{p'-1})$. Since g(x) mod p is a divisor of $x^{p'-1} - 1$ it follows that for some i we must have $g(\alpha_i) = 0$. Since g is irreducible mod p, the expressions

$$(8.23) a_{n} + a_{i}\alpha_{i} + \cdots + a_{r-1}\alpha_{i}^{r-1}$$

where the a_i are multiples of the unit element of \mathfrak{F} must all be different from 0 and thus also different from each other. Otherwise g(x) mod p would have a factor in common with a polynomial of degree < r. Thus 8.23 presents p' different elements of \mathfrak{F} and hence every element of \mathfrak{F} . But the correspondence $f(a_i) \leftrightarrow f(x)$ while \mathfrak{F} with the problem of \mathfrak{F} and \mathfrak{F} is in the field \mathfrak{F} of residues mod (g(x), p) is clearly an isomorphism. Thus any two fields \mathfrak{F} , \mathfrak{F}' are isomorphic to \mathfrak{F} and hence isomorphic to each other.

In an abstract sense we have therefore only one Galois field with p' marks. We shall denote this Galois field by G.F.(p').

If x in the field of residues mod (f(x), p) does not satisfy any equation $x^m - 1 \equiv 0(f(x), p)$ with $m < p^{r-1}$, then x is a primitive root. On the other hand if α is a primitive root of G.F.(p') then α must satisfy an irreducible equation of degree r. Thus if we wish for convenience to have G.F.(p') presented by the residues mod (f(x), p) in such a way that x is a primitive root, then we have to remove from $x^{p'-1} - 1$ all factors which are factors of $x^m - 1$ for any m < p' - 1. The remaining polynomial has as its roots all the primitive roots of G.F.(p') and must therefore have by Theorem 8.3 the degree $\phi(p'-1)$. We shall call it the cyclotomic polynomial of order p'-1.

To construct, for instance, G.F.(2³) we first form the cyclotomic polynomial of order $2^3 - 1 = 7$. Its degree is $\phi(7) = 6$. Removing the root 1 from $x^7 - 1$ we obtain

$$x^6 + x^5 + x^4 + x^3 + x^2 + x + 1$$
.

This polynomial must mod 2 decompose into 2 factors of degree 3 each. Thus

$$(x^6 + x^5 + x^4 + x^3 + x^2 + x + 1)$$

$$= (x^3 + ax^2 + bx + c)(x^3 + \bar{a}x^2 + bx + \bar{c})(2)$$

Hence

$$\vec{cc} = 1(2), c = \vec{c} = 1(2), b + \vec{b} = 1(2). \text{ Let } b = 0, \vec{b} = 1(2)$$

Then
$$\bar{a}c + a\bar{c} + b\bar{b} \equiv a + \bar{a} \equiv 1(2) c + \bar{c} + a\bar{b} + b\bar{a} \equiv a \equiv 1(2)$$
.

Hence a = 1(2), $\bar{a} = 0(2)$ and

$$x^6 + x^3 + x^4 + x^3 + x^2 + x + 1$$

www.dbrautibrary.org.in

 $(x^3 + x^2 + 1)(x^3 + x + 1)(2)$.

It is left to the reader to construct G.F.(23) and 7 orthogonal

Latin squares of side 8. For higher values of p'-1 it is rather laborious to find mod p irreducible polynomials of degree r by decomposing the

cyclotomic polynomial of order p' - 1. It is however easy to find irreducible polynomials in other ways, if we are willing to forego the advantage of having x as a primitive root. For instance, if p is odd then there always exist residues a for which $x^2 = a(p)$ is not solvable. Then $x^2 - a$ is irreducible mod p. The polynomial $x^3 - x$ is identically 0 mod 3; thus

 $x^3 - x - 1$ is irreducible mod 3 since it otherwise would have a linear factor mod 3. The polynomial $x^4 + x + 1$ is irreducible mod 2. Obviously it does not have the root 0 or 1, thus the only possible decomposition would be of the form

$$x^4 + x + 1 = (x^2 + bx + 1)(x^2 + b'x + 1)(2).$$

From which it would follow that b + b' = 1(2) and b + b' =0(2) which is impossible. With these and similar considerations one easily obtains the following irreducible polynomials:

mod 2
$$x^2 + x + 1$$
, $x^3 + x + 1$, $x^4 + x + 1$, $x^5 + x^2 + 1$,

$$mod 3$$
 $x^2 + x - 1, x^3 - x + 1,$

$$\mod 5 \qquad x^2 + 2,$$

$$\mod 7 \qquad x^2 + 1.$$

These polynomials take care of all Galois fields with less than 63 elements and these satisfy all needs that have arisen so far in the design of experiments.

From Theorem 8.6 and Theorem 8.1 we see that a set of m-1 orthogonal Latin squares of side m can always be constructed, if m is the power of a prime. If m is not the power of a prime then m may be decomposed into prime powers.

$$m = p_1^{\text{WW.dbraulibrau}}(p_1 \text{ord.pn}).$$

We then construct the following system. We consider "points".

$$\gamma = (g^{(1)}, g^{(2)}, \cdots, g^{(r)}), \qquad g^{(r)} \subset G.F.(p_r^{(rr)}).$$

We define addition and multiplication by the rules

$$\gamma_1 \overset{*}{\times} \gamma_2 = (g_1^{(1)}, \cdots, g_1^{(s)}) \overset{*}{\times} (g_2^{(1)}, \cdots, g_2^{(s)})$$

= $(g_1^{(1)} \overset{*}{\times} g_2^{(1)}, \cdots, g_1^{(s)} \overset{*}{\times} g_2^{(s)}).$

The system thus constructed is not a field since, for instance, the element $(0, 1, \dots, 1)$ has no inverse in multiplication. However, the postulates I-IV for addition and I-III for multiplication and postulate V are fulfilled. All the "points" which have no 0 among their coordinates possess inverses.

Let

$$g_1^{(i)} = 1, \qquad g_2^{(i)}, \cdots, g_{n^{(i)}-1}^{(i)}$$

be the marks of G.F. $(p_i^{e_i})$, then if $r = \min_i(p_i^{e_i} - 1)$ the "points"

$$(8.24) \gamma_i = (g_i^{(1)}, g_i^{(2)}, \cdots, g_i^{(s)}), 0 < j \le r$$

possess inverses and also $\gamma_i = \gamma_i$ does if $i \neq j$. Now we number the points γ in such a way, that the first r elements are given by 8.24 and form the r arrays.

We prove first that L_i is a Latin square. Suppose the α th row would contain an element twice then

www.phraulibrary.org.in
$$\gamma_i = \gamma_i \gamma_o + \gamma_i$$

from which $\gamma_k = \gamma_l$, k = l follows. Suppose that the *i*th column contains the same element twice, then

$$\gamma_i + \gamma_i \gamma_a = \gamma_i + \gamma_i \gamma_{\theta}$$
 $j \leq r$

and since γ_i possesses an inverse this implies $\gamma_a = \gamma_{\theta}$.

We shall now prove that L_i is orthogonal to L_i if $i \neq j$. Assume that they were not orthogonal. Then in superimposing L_i on L_i we should have two compartments in the resulting square containing the same pair of "points". If this pair occurs in the σ th row and the σ th column and in the σ th row and the σ th column, we should have

$$\gamma_i \gamma_{\alpha} + \gamma_{\beta} = \gamma_i \gamma_{\alpha} + \gamma_{\tau},$$

$$\gamma_i \gamma_{\alpha} + \gamma_{\beta} = \gamma_i \gamma_{\alpha} + \gamma_{\tau}.$$

Hence

$$(8.26) (\gamma_i - \gamma_i)\gamma_\alpha = (\gamma_i - \gamma_i)\gamma_\sigma$$

and since $\gamma_s - \gamma_t$ possesses an inverse 8.26 implies $\gamma_s = \gamma_t$ and consequently $\gamma_t = \gamma_t$. Thus we have

THEOREM 8.8: Let $g_{i_1}^1$, $g_{i_2}^{(2)}$, \cdots , $g_{i_s}^{(s)}$ denote the elements of G.F. $(p_1^{s_1})$, \cdots , G.F. $(p_s^{s_s})$ respectively where $g_0^{(s)}$ is the 0 element and $g_1^{(s)}$ the unit element of G.F. $(p_s^{s_s})$. Form the points

$$\gamma = (g_{i_1}^{(1)}, g_{i_2}^{(2)}, \cdots, g_{i_t}^{(s)})$$

which are multiplied and added by multiplying and adding their coordinates. Let further

$$\gamma_i = (g_i^{(1)}, \dots, g_i^{(s)}), \qquad 0 < j \le r = \min(p_i^{(s)} - 1)$$

and number the remaining points in any arbitrary way from r+1 to $m=p_1^{e_1}\cdots p_s^{e_s}$ in such a way that $\gamma_m=0=(g_0^{(1)},\cdots,g_0^{(s)})$. Then the arrays

$$0 \qquad 1 \qquad \cdots \qquad \gamma_{m-1}$$

$$\gamma_{i} \qquad \gamma_{i} + 1 \qquad \overset{\text{www.dbraulibrary.org.in}}{\cdots \qquad \gamma_{i+1} \gamma_{m-1}}$$

$$L_{i} = \gamma_{i} \gamma_{2} \qquad \gamma_{i} \gamma_{2} + 1 \qquad \cdots \qquad \gamma_{i} \gamma_{2} + \gamma_{m-1} \qquad (j = 1, \cdots, r)$$

$$\gamma_{i} \gamma_{m-1} \qquad \gamma_{i} \gamma_{m-1} + 1 \qquad \cdots \qquad \gamma_{i} \gamma_{m-1} + \gamma_{m-1}$$

form a set of r orthogonal Latin squares.

This result is the best that has been obtained so far. No case of more than $r = \min_i (p_i^* - 1)$ orthogonal squares is known to date. Tarry (Le Probleme de 36 Officiers. Comptes Rendus de'l Association Française pour L'avancement des Sciences II (1901) pp. 170-203) found by a skillful tactical enumeration that no 6 sided orthogonal pair exists. For numbers larger than 6 which are not powers of a prime the problem is completely unsolved although it has been considered by mathematicians

^{&#}x27;After completion of this manuscript R. H. Bruck and H. J. Ryser (Canad. J. of Math. Vol. 1, pp. 88-93) proved the non-existence of m-1 orthogonal squares of side m if $m \equiv 1, 2$ (4) and the square free part of m is divisible by a prime of the form 4k + 3.

long before Latin squares were applied in designing experiments.

It can readily be shown that no more than m-1 orthogonal Latin squares of side m can be constructed. For we may always arrange the numbering in the Latin squares in such a way that the first row is 1, 2, ..., m. Then in the remaining compartments different Latin squares must contain different numbers which must also be different from the column number. Thus at most (m-1) Latin squares of side m can occur in a set of orthogonal Latin squares.

Historically it may be remarked that the first proof of the existence of (m-1) orthogonal Latin squares if m is a prime power seems to have been given by McNeish. (Annals of Mathematics, Vol. XIII, pp. 221-227.) The methods for the construction of orthogonal Latin squares presented in this book were found independently obgain! I. Stevens (Nature, Sept. Jose (3, 1938) and by R. C. Bose (Sankhya, Nov., 1938).

The Construction of Incomplete **Balanced Block Designs**

IN THE CONSTRUCTION of incomplete balanced block designs finite projective geometries have been utilized and yield whole series of these designs. For our purposes it will be sufficient to consider finite analytic geometries. The points of these geometries are defined as follows. We consider G.F.(pⁿ). A point in the m dimensional finite geometry P.G.(m, p^{*}) is an ordered set of m + 1 elements of G.F. (p^n) , not all of which are equal to 0. Two sets (g_1, \dots, g_{m+1}) , (g'_1, \dots, g'_{m+1}) represent the same point if $g_i = \lambda g'_i$, $i = 1, \dots, m+1, 0 \neq \lambda \subset G.F.(p^n)$. For any two distinct points p_1^{branch} parameter p_2^{max} , p_2^{max} . (g'_1, \dots, g'_{m+1}) we define as the line joining them the set of all points of the form

$$\lambda_1 p_1 + \lambda_2 p_2 = (\lambda_1 g_1 + \lambda_2 g_1', \dots, \lambda_1 g_{m+1} + \lambda_2 g_{m+1}'),$$

$$(9.1)$$

$$\lambda_1, \lambda_2 \subset G.F.(p^n),$$

where at least one of the λ 's is different from 0.

The system of points and lines obtained in this manner is called the analytic projective geometry of $G.F.(p^n)$ of m di-

mensions and is denoted by P.G. (m, p^*) .

We first compute the number of points in P.G. (m, p^n) . There are $p^{n(m+1)}$ ordered sets of m+1 marks of G.F. (p^n) . Since we excluded the set $(0 \cdots 0)$ there remain $p^{n(m+1)} - 1$ ordered sets at least one of whose elements is different from 0. These may be arranged in groups of p^*-1 sets all of whose elements represent the same points, since $(g_1, \dots, g_{m+1}) = (\lambda g_1, \dots, g_m)$ λg_{m+1}) for every $\lambda \neq 0$ in G.F. (p^n) . Hence there are

$$(9.2) \frac{p^{n(m+1)}-1}{p^n-1}=1+p^n+\cdots+p^{nm}$$

distinct points. The lines are given in the form $\lambda_1 p_1 + \lambda p_2$ where p_1 and p_2 are distinct points. The points of this line are given by their line coordinates λ_1 , λ_2 . Two points λ_1 , λ_2 ; μ_1 , μ_2 will be distinct if $(\lambda_1, \lambda_2) \neq \nu(\mu_1, \mu_2)$ for all ν in G.F.(p). Hence the points of a line form an analytic one dimensional geometry and the line has therefore $1 + p^*$ points.

We now consider the k dimensional subspaces of P.G.(m, p). Let p_1, \dots, p_{k+1} be k+1 linearly independent points. That is to say

(9.3)
$$\lambda_1 p_1 + \cdots + \lambda_{k+1} p_{k+1} = (0, \dots, 0)$$

implies $\lambda_1 = \cdots = \lambda_{k+1} = 0$. We consider then all the points of the form $\lambda_1 p_1 + \cdots + \lambda_{k+1} p_{k+1}$. Assume that two of these points are equal. Then

its are equal. Then
$$\lambda_{i}p_{1} + \cdots + \lambda_{k+1}p_{k+1} = \nu(\mu_{1}p_{1} + \cdots + \mu_{k+1}p_{k+1}),$$

$$(\lambda_{1} - \nu\mu_{1})p_{1} + \cdots + (\lambda_{k+1} + \nu\mu_{k+1})p_{k+1} = (0, \dots, 0).$$

Since p_1 , \cdots , p_{k+1} are independent this implies

$$\lambda_1 = \nu \mu_1$$
, ..., $\lambda_{k+1} = \nu \mu_{k+1}$.

We can now introduce coordinates λ_1 , ..., λ_{k+1} in the k dimensional subspaces. Clearly for $k \geq 1$ the subspaces contain for every two points also the line joining them. Hence every k dimensional subspace of a P.G. (m, p^n) is itself a P.G. (k, p^n) and has therefore $1 + p^n + \cdots + p^{kn}$ points. We now compute the number of P.G. (k, p^n) contained in a P.G. (m, p^n) . Every P.G. (k, p^n) is determined by a set of (k + 1) independent points. The first of these, p_1 , may be chosen in $1 + p^n + \cdots + p^{nm}$ ways. For p_2 we have then $p^n + \cdots + p^n$ choices. For the third p_3 we may choose any point not on the line through p_1 and p_2 which leaves us $p^{2n} + \cdots + p^{nm}$ choice. After the lth point (l < k + 1) has been chosen, we may choose for the (l + 1)th point any point not in the P.G.(l - 1) determined by p_1 , ..., p_1 . Thus $1 + p^n + \cdots + p^{nm}$

points are excluded and $p^{in} + \cdots + p^{mn}$ are left to cho from. Thus the number of distinct ordered sets of k+1 in

pendent points in P.G. (m, p^*) is

$$(9.4) (1 + \cdots + p^{mn}) \cdots (p^{kn} + \cdots + p^{mn}).$$

The number of ordered sets of (k+1) independent points in P.G. (k, p^*) is by 9.4

$$(1 + \cdots + p^{kn}) \cdots (p^{(k-1)n} + p^{kn})p^{kn}$$

Hence the number of P.G. (k, p^n) contained in P.G. (m, p^n) becomes

$$(9.5) \frac{(1+\cdots+p^{mn})(p^{n}+\cdots+p^{mn})\cdots(p^{kn}+\cdots+p^{kn})}{(1+\cdots+p^{kn})\cdots(p^{(k-1)n}+p^{kn})p^{kn}}$$

We finally want to find the number of $P.G.(s, p^n)$ in P.G. (m, p^n) which contain a given P.G. (k, p^n) . We first choose a point p_{k+2} not contained in the results of $P.G.(k, p^n)$. This point p_{k+2} may be chosen out of $p^{(k+1)n} + \cdots + p^{mn}$ points. We then choose p_{k+3} out of the $p^{(k+2)n} + \cdots + p^{mn}$ points not contained in the P.G. $(k+1, p^n)$ which contains p_{k+2} and the given P.G. (k, p^n) . Continuing in this manner we can obtain a P.G. (s, p^n) containing the given P.G. (k, p^n) in $(p^{(k+1)n} + \cdots + p^{mn}) \cdots (p^{m} + \cdots + p^{mn})$ ways. Putting m = s we see that every P.G. (s, p^n) is obtained in this manner in $(p^{(k+1)n} + \cdots + p^{mn}) \cdots (p^{(s-1)n} + p^{sn})p^{sn}$ ways. Hence for s > k we must have

$$\frac{(p^{(k+1)n} + \cdots + p^{mn}) \cdots (p^{sn} + \cdots + p^{mn})}{(p^{(k+1)n} + \cdots + p^{sn}) \cdots (p^{(s-1)n} + p^{sn})p^{sn}}$$

different P.G.(s, p^n) in P.G.(m, p^n) which contain a given P.G. (k, p^n) .

Summarizing we have:

- 1. Every P.G.(m, p^n) contains exactly $1 + p^n + \cdots + p^{mn}$ points.
 - Every P.G.(m, pⁿ) contains exactly

$$\frac{(1+p^{n}+\cdots+p^{mn})\cdots(p^{kn}+\cdots+p^{mn})}{(1+p^{n}+\cdots+p^{kn})\cdots(p^{(k-1)n}+p^{kn})p^{kn}} \qquad P.G.(k, p^{n}).$$

3. Every P.G. (k, p^n) in P.G. (m, p^n) is contained in

$$p(p^{(k+1)n} + \cdots + p^{mn}) \cdots (p^{m} + \cdots + p^{mn}) \cdots (p^{(k+1)n} + \cdots + p^{mn}) \cdots (p^{(k+1)n} + \cdots + p^{mn}) \cdots (p^{(k+1)n} + p^{mn}) p^{(n)}$$

P.G. (s, p^*) 's for s > k.

For k = 0, 1 one obtains in particular:

A. Every point is contained in

$$r = \frac{(p^n + \cdots + p^{mn}) \cdots (p^{m} + \cdots + p^{mn})}{(p^n + \cdots + p^{mn}) \cdots (p^{(n-1)n} + \cdots + p^{mn})} \cdots (p^{(n-1)n} + \cdots + p^{mn})$$

P.G.(s,
$$p^n$$
) of a P.G.(m , p^n) $m \ge s > 0$

B. Every line is contained in in

$$\lambda = \frac{(p^{2n} + \cdots + p^{mn}) \cdots (p^{n} + \cdots + p^{mn})}{(p^{2n} + \cdots + p^{nn}) \cdots (p^{n})} + \frac{p^{mn}}{(p^{nn})}$$

P.G.
$$(s, p^n)$$
 for $m \ge s > 1$.

Every P.G.(s, p^n) contains with every pair of points also the whole line joining them. Thus every pair of points is contained in λ different P.G.(s, p^n).

We may now identify the points with varieties and the P.G. (s, p^n) with blocks. Then we have the following theorem.

Theorem 9.1: The P.G.(s, p^n) contained in a P.G.(m, p^n) form a balanced incomplete block design with the parameters

(9.6)
$$b = \frac{(1 + p^{n} + \dots + p^{mn}) \cdot \dots \cdot (p^{sn} + \dots + p^{mn})}{(1 + \dots + p^{sn}) \cdot \dots \cdot (p^{(s-1)n} + p^{sn})p^{sn}}$$

$$= b(s, m, p^{n}), \quad P. \subseteq (p, p^{n}) - b(s, p^{n})$$

$$v = 1 + p^n + \dots + p^{mn} = v(m, p^n), \text{ point } p \in \{m, p^n\}$$

$$k = 1 + p^n + \dots + p^{sn} = k(s, p^n),$$

$$To \text{ where } p \in \{m, p^n\}$$

block pize = points in PCa(Bir)

$$r = \frac{(p^{n} + \dots + p^{mn}) \cdots (p^{sn} + \dots + p^{mn})}{(p^{n} + \dots + p^{sn}) \cdots (p^{(s-1)n} + p^{sn})p^{sn}}$$

$$= r(s, m, p^{n}), \qquad \text{for } 0 \text{ for } 0 \text{ fo$$

We next consider the points in P.G.(m, p") common to a given P.G. $(m-1, p^n)$ and a given P.G. (s, p^n) not contained in it. Let p_1 be a point in the P.G.(s, p^n) which is not contained in the P.G. $(m-1, p^n)$. Let q_1^{th} raulibrary beginninearly independent points in the P.G. $(m-1, p^n)$. Then p_1, q_1, \dots, q_m are m + 1 linearly independent points and hence every point of P.G. (m, p^n) is of the form

$$\lambda_1 p_1 + \lambda_2 q_1 + \cdots + \lambda_{m+1} q_m$$

Now let p_1 , p_2 , ..., p_{s+1} be s+1 linearly independent points of the given P.G. (s, p^n) . Then for every i we must have an equation < ?

(9.7)
$$p_i = \lambda_1^{(i)} p_1 + \lambda_2^{(i)} q_1 + \dots + \lambda_{m+1}^{(i)} q_m .$$

Therefore $p_i'=p_i-\lambda_1^{(i)}p_1$, $i=2,\cdots,s+1$, is contained in the P.G. $(m-1, p^*)$. The points p_2', \dots, p_{s+1}' are obviously linearly independent. Hence the P.G.(s - 1, p") of points of the form $\lambda_2 p_2' + \cdots + \lambda_{i+1} p_{i+1}'$ is contained in the P.G. $(m-1, p^n)$. But these are all the points of the given P.G. (s, p^n) which are contained in the P.G. $(m - 1, p^n)$. If there were another point p'_1 of the P.G.(s, p'') contained in the P.G. $(m-1, p^n)$ and linearly independent of p_2', \dots, p_{s+1}' , then $\lambda_1 p_1' + \cdots + \lambda_{i+1} p_{i+1}'$ would present every element in the P.G.(s, p^n), contrary to the hypothesis that not all its points are contained in the P.G. $(m-1, p^n)$.

Now by deleting from a P.G. (m, p^n) any given P.G. $(m-1, p^n)$ and all its points one obtains another system of points and lines which is termed the finite analytic Euclidean Geometry E.G. (m, p^n) of m dimensions. Every P.G. (s, p^n) contained in P.G. (m, p^n) but not in the P.G. $(m-1, p^n)$ becomes an E.G. (s, p^n) , since by deleting a P.G. $(m-1, p^n)$ from P.G. (m, p^n) we also delete a P.G. $(s-1, p^n)$ from each of these P.G. (s, p^n) contained in P.G. (m, p^n) . The number of points of an E.G. (m, p^n) is

$$v(m, p^n) - v(m-1, p^n) = p^{mn}$$

The number of E.G.(s, p^n) contained in E.G.(m, p^n) is $b(s, m, p^n) - b(s, m - 1, p^n)$

The number of E.G.(s, p^n) containing a given E.G.(k, p^n) is the same as the number of E.G.(k, p^n) containing a given P.G.(k, p^n). Hence we have

Theorem 9.2: The E.G.(s, p^*) contained in an E.G.(m, p^*) form a balanced incomplete block design with the parameters

$$b = b(s, m, p^{n}) - b(s, m - 1, p^{n}),$$

$$v = p^{mn},$$

$$k = p^{n},$$

$$r = r(s, m, p^{n}),$$

$$\lambda = \lambda(s, m, p^n).$$

As an example we construct the lines of the P.G.(3, 2) and the E.G.(3, 2). Applying 9.6 and 9.8 we see that we have in the P.G.(3, 2) exactly 35 lines and 15 points and in the E.G. (3, 2) exactly 28 lines and 8 points. Every point must occur in 7 lines. Every line of the P.G.(3, 2) contains 3 points and

every line of the E.G.(3, 2) contains 2 points. Hence the balanced block designs which we shall obtain have the parameter b = 35, v = 15, r = 7, k = 3, $\lambda = 1$;

b = 28, v = 8, r = 7, k = 2, $\lambda = 1$.

The second design consists simply of all pairs of points and can easily be obtained directly. G.F.(2) consists of the two elements 0, 1 with the rules of composition 0 + 0 = 0, 0 + 1 = 1 + 0 = 1, 1 + 1 = 0.

The points are then given by

$$p_1 = 1000$$
, $p_5 = 1100$, $p_9 = 0101$, $p_{13} = 1011$, $p_2 = 0100$, $p_6 = 1010$, $p_{10} = 0011$, $p_{14} = 0111$, $p_3 = 0010$, $p_7 = 1001$, $p_{11} = 1110$, $p_{15} = 1111$. $p_4 = 0001$, $p_8 = 0110$, $p_{12} = 1101$,

The lines can be obtained by taking pairs of points, for instance, p_1 and p_2 and forming $\lambda_1 h_1 h_2 h_3 p_2$ for $(\lambda_1, \lambda_2) = (0, 1)$, (1, 0), (1, 1). Thus for instance the points in the line p_1 , p_2 are p_1 , p_2 and $p_1 + p_2 = p_3$. The lines through p_1 , p_3 and p_2 , p_5 need not be constructed if the line through p_1 , p_2 has already been written down. Proceeding systematically in this way one obtains 35 lines.

way one obtains obtains
$$p_1p_2 p_5$$
, $p_2p_5 p_8$, $p_3p_5 p_{11}$, $p_4p_{11}p_{15}$, $p_6 p_{12}p_{14}$, $p_1p_3 p_6$, $p_2p_4 p_6$, $p_3p_7 p_{13}$, $p_5p_6 p_8$, $p_7 p_8 p_{15}$, $p_1p_4 p_7$, $p_2p_5 p_{11}$, $p_3p_9 p_{14}$, $p_6p_7 p_9$, $p_7 p_{11}p_{14}$, $p_1p_8 p_{11}$, $p_2p_7 p_{12}$, $p_3p_{12}p_{15}$, $p_5p_{10}p_{15}$, $p_8 p_9 p_{10}$, $p_1p_9 p_{12}$, $p_2p_{10}p_{14}$, $p_4p_5 p_{12}$, $p_5p_{13}p_{14}$, $p_8 p_{12}p_{13}$, $p_1p_{10}p_{13}$, $p_2p_{13}p_{15}$, $p_4p_6 p_{13}$, $p_6p_7 p_{10}$, $p_9 p_{11}p_{13}$, $p_1p_{14}p_{15}$, $p_3p_4 p_{10}$, $p_4p_8 p_{14}$, $p_6p_9 p_{15}$, $p_{10}p_{11}p_{12}$.

If we delete from this design all the points with last coordinate 0, that is to say, the plane $\lambda_1 p_1 + \lambda_2 p_2 + \lambda_3 p_3$ then we must obtain the E.G.(3, 2). The deleted points are p_1 , p_2 , p_3 , p_5 ,

 p_6 , p_8 , p_{11} . The reader may verify that the remaining sets consist of all possible pairs of the remaining 28 points. To give also a non-trivial example of a finite Euclidean geometry we shall construct the E.G.(2, 3). The P.G.(2, 3) has $3^2 + 3 + 1 = 13$ points; the E.G.(2, 3) has 9 points. G.F.(3) consists of the marks 0, 1, -1 considered mod 3. The points of P.G.(2, 3) are: $p_1 = 1,0,0, \quad p_5 = 1,0,1, \qquad p_9 = 1,0,-1, \qquad p_{10} = 0,-1,1, \qquad p_{10} = 0,-1,1, \qquad p_{10} = 0,-1,1, \qquad p_{10} = 0,-1,1, \qquad p_{10} = 0,-1,1,1, \qquad p_{10} = 0,0,1, \qquad p_{10} = 1,1,1,1, \qquad p_{10} = 1,1,1,1,1, \qquad$

 $p_4=1,1,0$, $p_8=1,-1,0$, $p_{12}=1,1,-1$, www.dbraulibrary.org.in

The line through p_1 and p_2 consists of the points p_1 , p_2 , $p_1+p_2=p_4$, $p_1-p_2=p_8$. Systematically proceeding as before one obtains the lines:

 $p_7p_8p_9p_{13}$,

$$p_1p_2 \ p_4 \ p_8$$
 , $p_2p_3p_6 \ p_{13}$, $p_3p_5p_{16}p_{11}$, $p_1p_3 \ p_5 \ p_9$, $p_2p_5p_7 \ p_{11}$, $p_4p_5p_{10}p_{13}$, $p_4p_5p_{10}p_{13}$, $p_1p_6 \ p_7 \ p_{10}$, $p_2p_9p_{10}p_{12}$, $p_4p_6p_9 \ p_{11}$, $p_4p_{11}p_{12}p_{13}$, $p_3p_4p_7 \ p_{12}$, $p_5p_6p_8 \ p_{12}$,

Now we delete one line, say the first and all the points on it and obtain

 $p_3 \ p_5 \ p_9 \ , \qquad p_3 p_6 \ p_{12} \ , \qquad p_3 p_7 \ p_{12} \ , \qquad p_6 p_9 p_{11} \ , \ p_6 \ p_7 \ p_{10} \ , \qquad p_5 p_7 \ p_{11} \ , \qquad p_5 p_{10} p_{11} \ , \qquad p_5 p_6 p_{12} \ , \ p_{11} p_{12} p_{13} \ , \qquad p_9 p_{10} p_{12} \ , \qquad p_5 p_{10} p_{13} \ , \qquad p_7 p_9 p_{13} \ .$ This is the Fig. (

This is the E.G.(2, 3).

The E.G.(2, p^n) can also easily be obtained from a set of

 p^n-1 orthogonal Latin squares of side p^n which were constructed from a Galois field. We take as points the compartments of the Latin square numbered from 1 to p^{2n} . The lines are then given by the columns, the rows, and by the sets of compartments whose *i*th number is α , $(\alpha=1,\cdots,p^n)$, $(i=1,\cdots,p^n-1)$. These lines are arranged in m+1 sets of m parallel lines each. Thus for instance the rows are parallel to each other. To obtain the P.G. $(2,p^n)$ one adds additional points, the same point to each line of a set of parallel lines and different points to intersecting lines, and takes these additional points into one additional line.

Finite geometries furnish whole series of balanced incomplete block designs. However, only a few of these are at present of practical interest since the number of replications should in most practical cases not exceed 10

Most practical cases not exceed 10^{a} authorary organically other series of these designs can be obtained by applying two theorems first proved by R. C. Bose. (Annals of Eugenics, 9 (1939) pp. 358-399.) To formulate these two theorems we need the concept of a module. A module is a system of elements such that to each pair of elements a, b there is uniquely defined a sum a + b satisfying the postulates I, II, III, IV for the addition in a field. For instance the residues mod m form a module for every m. A module with a finite number of elements is called a finite module. If \mathfrak{M} has n elements then \mathfrak{M} is called a module of order n.

Let \mathfrak{M} now be a module of order n and let m varieties $A_1^{(i)}$, ..., $A_m^{(i)}$ correspond to every element $A^{(i)}$ of the module. We may form blocks of these varieties.

$$(9.9) \qquad (A_{i_1}^{(\alpha_1)}, \cdots, A_{i_k}^{(\alpha_k)}), \qquad (A_{i_1}^{(\beta_1)}, \cdots, A_{i_k}^{(\beta_k)}).$$

From every block of k varieties we may write k(k-1) expressions of the form $A_{\gamma} - B_{\delta} = (A - B)_{\gamma\delta}$. This expression is called a difference of type $\gamma\delta$.

Taking for instance as our module the residues mod 5 we could form the blocks

$$(0_1, 1_2, 2_1), (0_2, 3_1, 4_2).$$

Then the differences are 1_{21} , 2_{11} , 4_{12} , 1_{12} , 3_{11} , 4_{21} from the first block, 3_{12} , 4_{22} , 2_{21} , 1_{21} , 1_{22} , 4_{12} from the second block. The differences of type $\alpha\beta$ are called pure if $\alpha = \beta$ and mixed if $\alpha \neq \beta$.

If in t blocks every pure difference except 0 is repeated λ times and every mixed difference the same number λ of times, then the differences are termed symmetrically repeated.

We shall now prove the following theorem.

THEOREM 9.3: Let \mathfrak{M} be a module containing the elements $v^{(a)}, \cdots, v^{(n-1)}$ and let m varieties $v^{(i)}_1, \cdots, v^{(i)}_m$ correspond to every element $v^{(i)}$. The variety $v^{(a)}_i$ is said to belong to the jth class. Suppose that there exist t blocks of elements B_1, \cdots, B_t such that

1. The varieties in each block are different from each other.

2. Among the elements in B_1 , B_2 , \cdots , B_i exactly r varieties belong to each of the m classes.

3. The differences arising from B_1 , \cdots , B_t are symmetrically repeated, each occurring λ times.

If

$$B = (v_{\alpha_1}^{(i_1)}, \cdots, v_{\alpha_k}^{(i_k)})$$
let

and $v^{i_*} + \theta = v^{i_*}$ let

$$(9.10) B_{\theta} = (v_{\alpha_{\lambda}}^{(i_{\lambda})}, \cdots, v_{\alpha_{k}}^{(i_{k})}).$$

Form the blocks $B_{i\theta}$ for all i and all $\theta \subset \mathfrak{M}$, then:

1. In the blocks B, every variety occurs r times.

 $^{\circ}$ 2. Any two varieties occur together in the same block exactly $^{\lambda}$ times.

Corollary: If each block B_i contains the same number of varieties the blocks $B_{i\theta}$ form an incomplete balanced block design.

Proof of Theorem 9.3: To every pair of elements v, v' of \mathfrak{M} there is exactly one θ such that $v + \theta = v'$. Hence since r of the varieties in B_1, \dots, B_s belong to the *i*th class, the variety

 v_i' will occur exactly r times. In order that a pair u_{α} , v_{β} of

varieties occurs exactly μ times in the blocks $B_{i\theta}$ it is necessary and sufficient that exactly μ times for u'_{α} and v'_{θ} in the same block

$$u' + \theta = u,$$

$$v' + \theta = v.$$

Hence u'-v'=u-v=d. Then $\theta=u-u'=v-v'$. Hence the pair u_{α} , v_{β} occurs exactly as many times as the difference d arises as a difference of type $\alpha\beta$ in the initial blocks B_1, \dots, B_t , that is to say $\mu=\lambda$ times. This proves the theorem.

As an example consider the group of residues mod 2t + 1 and the pairs

$$(1, 2t), (2, 2t - 1), \cdots, (t, t + 1)$$

Every residue different from 0 arises from these pairs just once. Now consider the blocks

nce. Now consider the blocks
$$(1_1, (2t)_1, 0_2), (2_1, (2t-1)_1, 0_2), \cdots, (t_1, (t+1)_1, 0_2);$$
 $(1_2, (2t)_2, 0_3), (2_2, (2t-1)_2, 0_3), \cdots, (t_2, (t+1)_2, 0_3);$ $(1_3, (2t)_3, 0_1), (2_3, (2t-1)_3, 0_1), \cdots, (t_3, (t+1)_3, 0_1);$ $(0_1, 0_2, 0_3).$

All pure differences arise exactly once from the first two elements of the first 3t blocks. All non 0 mixed differences of type 1,2 and type 2,1 arise from the first set of blocks, those of type 2,3 and type 3,2 from the second set and those of type 1,3 and 3,1 from the 3rd set. The mixed differences 0 arise 1,3 and 3,1 from the 3rd set. The mixed differences 0 arise from $(0_1, 0_2, 0_3)$. Since each block contains 3 varieties, we obtain by applying Theorem 9.3 an incomplete balanced block design with v = 6t + 3, b = (3t + 1) (2t + 1), r = 3t + 1, k = 3, $\lambda = 1$.

For instance let t=2, then 2t+1=5 and the initial blocks are $(1_1, 4_1, 0_2)$, $(2_1, 3_1, 0_2)$, $(1_2, 4_2, 0_3)$, $(2_2, 3_2, 0_3)$, $(1_3, 4_3, 0_1)$, $(2_3, 3_3, 0_1)$, $(0_1, 0_2, 0_3)$. We leave the construction of this design to the reader.

Let us now adjoin to the module $\mathfrak M$ the symbol ∞ with the rule of operation $\infty + a = \infty$. We shall now prove the following

THEOREM 9.4: Let \mathfrak{M} be a module with n elements $u_{i}^{(0)}$, ..., u'n-1). To every element u'a let there correspond m varieties $u_1^{(\alpha)}, \cdots, u_m^{(\alpha)}$, whilst one variety corresponds to the symbol ∞ . The variety u; a) is said to belong to the ith class and the varieties $u_i^{(a)}$ are called finite varieties. Suppose there exist t+s blocks B_1 , ..., B_t , B_1' , ..., B_s' , such that:

- 1. The varieties in each block are different from each other.
- 2. The blocks B1, . . . , B1 contain exactly k finite varieties each while B_1' , ..., B_k' contain exactly (k-1) finite varieties
- 3. Among the varieties in B_1 to each classy while banding the varieties in B_1' , ..., B_2' exactly
- 4. The differences arising from the finite varieties are symmetrically repeated, each occurring λ times.

We define the blocks B_{is} , B'_{is} as in Theorem 9.3.

Then the blocks B. , B', form an incomplete balanced block design with the parameters v = mn + 1, b = n(t + s), r = ns, k, λ .

From Theorem 9.3 it follows that every finite variety is repeated r = ns times and each pair of finite varieties occurs λ times. The variety ∞ occurs in each of the ns blocks $B_{i\theta}'$ hence co occurs also ns times. Also each finite variety occurs in the B_{is}' because of 3 exactly λ times. Hence ∞ occurs with every finite variety λ times together in the same block.

As an application we shall construct designs with v = 12t + 4, $b = (3t+1)(4t+1), r = 4t+1, k = 4, \lambda = 1 \text{ where } 4t+1$ is a power of a prime.

We take the elements of G.F.(4t + 1) with respect to addition as composition as our module \mathfrak{M} . Let x be a primitive root. We shall first show that there exist odd numbers α and q such that $(x^{\alpha} + 1)/(x^{\alpha} - 1) = x^{\alpha}$.

The non 0 elements of G.F.(4t + 1) are given by x^0, x^1, \dots ,

 x^{4i-1} . We form for every $\alpha \neq 0$ $(x^{\alpha} + 1)/(x^{\alpha} - 1)$. This is a non 0 mark of G.F.(4i + 1) if $\alpha \neq 2i$, since x is a primitive root $x^{2i} \neq 1$ and hence $x^{2i} = -1$. Hence for all values $\alpha \neq 0$, 2i we have

(9.12)
$$\frac{x^{\alpha} + 1}{x^{\alpha} - 1} = x^{\alpha}.$$

Clearly $x^{\alpha} = (x^{q} + 1)/(x^{q} - 1)$. Hence to every $\alpha \neq 0$, 2t belongs a unique value $q \neq 0$, 2t but among the residues mod 4t, $2, \dots, 2t - 1$, 2t + 1, \dots , 4t - 1 there are 2t odd residues but only 2t - 2 even residues. Hence to at least 2 odd residues there must belong an odd residue.

Now let 3 varieties correspond to each mark of G.F.(4t + 1). We form the (3t + 1) blocks

$$\begin{array}{lll} (x_1^{2i}, & x_1^{2i+2i}, & x_2^{2i+\alpha}, & x_2^{2i+\alpha}, & x_2^{2i+\alpha}); \\ \\ (x_2^{2i}, & x_2^{2i+2i}, & x_3^{2i+\alpha}, & x_3^{2i+2i+\alpha}); & i = 0, 1, \cdots, t-1 \\ \\ (x_3^{2i}, & x_3^{2i+2i}, & x_1^{2i+\alpha}, & x_1^{2t+2i+\alpha}); \\ \\ (\infty, 0_1, 0_2, 0_3). \end{array}$$

We observe first that $x^{2i} = -1$. We further put $x^{\alpha} + 1 = x^{\alpha}$, $x^{\alpha} - 1 = x^{\alpha}$, $x^{2i} - 1 = x^{\beta}$. Then we may choose α so that

$$(9.13) u - v \equiv \mathbf{1}(2).$$

Every class of varieties occurs 4t times in the first 3t blocks and once in the last block. The differences of type (1, 1) arise from the first and 3rd set of blocks and may be written as

$$(9.14) \ x^{2i+\epsilon_1 2t+\epsilon_2 \alpha} (x^{2t}-1) = x^{2i+2t\epsilon_1+\epsilon_2 \alpha+\beta}, \ (i=0, \cdots, t-1),$$

where ϵ_1 , ϵ_2 are either 1 or 0. These are 4t differences. We shall show that no two of them are equal. Suppose that

$$(9.15) x^{2i+\epsilon,2i+\epsilon,\alpha+\beta} = x^{2i+\epsilon',2i+\epsilon',\alpha+\beta}.$$

Then

$$x^{2(i-j)+2i(\epsilon_1-\epsilon'_1)+\alpha(\epsilon_2-\epsilon'_2)}=1.$$

Hence

$$(9.16) 2(i-j) + 2t(\epsilon_1 - \epsilon_1') \equiv -\alpha(\epsilon_2 - \epsilon_2')(4t).$$

Since α is odd it follows that $\epsilon_2 \equiv \epsilon_2'(2)$ and therefore $\epsilon_i = \epsilon_i$. Thus $i - j \equiv t(\epsilon_1 - \epsilon_1')(2t)$. Hence either $i - j \equiv 0(2t)$ or $i - j \equiv t(2t)$. Both of these congruences are impossible for $i \neq j$ since $i, j \leq t - 1$. Hence the 4t differences of type 1,1 are distinct and different from 0 and therefore must contain each of the 4t non 0 marks exactly once. Similarly, it may be shown that every mark of G.F. (4t + 1) occurs exactly once the mixed differences of type 2, 2 and 3, 3. Let us now consider the mixed differences of type 1, 2. These arise from the first set of blocks and from the last block only. Those from the first set of blocks may be written as

(9.17)
$$x^{2i+\epsilon_12i} - x^{2i+\alpha+\epsilon_12i} = x^{2i} \left(\pm 1 - \left(+-\right)x^{\alpha}\right).$$

Hence one obtains one of the four expressions

$$-x^{2i}(x^{\alpha}-1)=x^{2i+2i+1}, x^{2i}(x^{\alpha}-1)=x^{2i+1},$$

$$x^{2i}(x^{\alpha}+1) = x^{2i+u}, \qquad -x^{2i}(x^{\alpha}+1) = x^{2i+2i+u},$$
 either

hence either

$$x^{2i+\epsilon 2t+u}$$
 or $x^{2i+\epsilon 2t+v}$

We obtain thus 4t non zero marks of G.F.(4t + 1). We shall prove that they are all different. We first observe that

$$(9.18) x^{2i+\epsilon 2i+u} = x^{2i+\epsilon' 2i+u}$$

implies $i-j\equiv t(\epsilon'-\epsilon)(2t)$, which was already shown to be impossible. But

$$x^{2i+\epsilon 21+u} = x^{2i+\epsilon' 21+v}$$

implies u - v = 0(2) which contradicts 9.13. Thus each of the 4t non 0 marks of G.F. (4t + 1) occurs excatly once among the differences of type 1, 2. The proof for the other mixed differences is analogous. The 0 differences of mixed type all arise from the last block. Thus all the conditions of Theorem 9.4 are satisfied.

As an example let 4t + 1 = 9. G.F.(9) may be presented as the field of residues mod 3, $y^2 + 1$. G.F.(9) then consists of the 9 marks; 0, 1, -1, y, y + 1, y - 1, -y, -y + 1, -y - 1. x = (-y + 1) is a primitive root.

$$x = (-y + 1) \text{ is a primitive root.}$$

$$x^{2} = (-y + 1)^{2} = y^{2} + y + 1 = y,$$

$$x^{3} = (-y + 1)^{3} = y + 1, \quad x^{4} = -1,$$

$$(9.20)$$

$$x^{5} = y - 1, \quad x^{6} = -y, \quad x^{7} = 1, \quad x^{6} = 1.$$

$$\frac{x + 1}{x - 1} = \frac{-y - 1}{-y} = \frac{x^{3}}{x^{2}} = x.$$

Hence we may take $\alpha = 1$. The first set of initial blocks is then

$$(1_1, (-1)_1, x_2, -x_2), (x_1^2, -x_1^2, x_2^3 - x_2^3).$$

Thus the initial blocks are
$$[(1)_1; (-1)_1; (-y+1)_2; (y-1)_2],$$

$$[y_1; -y_1; (y+1)_2; (-y-1)_2];$$

$$[(1)_2; (-1)_2; (-y+1)_3; (y-1)_3],$$

$$[y_2; -y_2; (y+1)_3; (-y-1)_3];$$

$$[(1)_3; (-1)_3; (-y+1)_1; (y-1)_1],$$

$$[y_3; -y_3; (y+1)_1; (-y-1)_1];$$

$$(\infty; 0_1; 0_2; 0_3).$$

The completion of the design is left to the reader. The designs constructed from Theorem 9.3 have for m=1 the property that every variety occurs exactly t times in every position in the blocks. This is of importance if the position in the block has an effect on the yield. The analysis of variance of such designs, when the block position has an effect on the yield, is straight forward and is left to the reader. Of particular interest are the so-called symmetrical designs

with v = b, r = k. From any symmetrical design two other designs can be obtained. The derived design obtained by retaining in the blocks B_2 , \cdots , B_b only those varieties which are in B_1 and the residual design which is obtained by deleting from the design all the varieties in B_1 . In order to show that these configurations are really incomplete balanced block designs we shall show that every block has exactly a varieties in common with diraulibrary organic in this result it follows that the derived and residual designs are incomplete balanced block designs with the parameters: $k, v - 1, k - 1, \lambda, \lambda - 1$ and v - k, v - 1, k $k - \lambda$, λ respectively. As an example for the processes of residuation and derivation we shall consider the design 25, 25, 9, 9, 3. This design was constructed by Bhattacharya (Bull. Calcutta Math. Soc. 36 (1945) pp. 91-96) and is not yet incorporated in the statistical tables of Fisher and Yates, which listed all incomplete balanced block designs with $r \le 10$ which were known up to 1943. Bhattacharya's design is as follows:

(9.20)5, 6,11,12,17,20,23; 1,3, 5, 7,10,12,18,21,24;

- 1, 2, 9, 10, 15, 16, 17, 21, 25;1,3, 9,11,14,16,18,22,23;

17,18,19,20,21,	22,23,24,25;	ilDi
From 9.20 we	obtain by the	process of residuation deleting
all the varieties $r = 9, k = 6, \lambda$		\mathbf{r}_{a} thebensiga $\mathbf{g}_{.i}$ in 16 , $b=24$,
(9.21)	2	71.
1,2,	5, 6,11,12;	1,3, 5, 7,10,12;
1,2,	9,10,15,16;	1,3, 9,11,14,16;
1,2,	7, 8,13,14;	1,3, 6, 8,13,15;
3,4,	7, 8, 9,10;	2,4, 6, 8, 9,11;
3,4,1	1,12,13,14;	2,4,10,12,13,15;
, O~	5, 6,15,16;	2,4, 5, 7,14,16;
1,4,	5, 8,10,11;	5,6, 9,10,13,14;
1,4,	9,12,14,15;	5,7, 9,11,13,15;
1,4,	6, 7,13,16;	5,8, 9,12,13,16;
2,3,	6, 7, 9,12;	7,8,11,12,15,16;
	10,11,13,16;	6,8,10,12,14,16;
	5, 8,14,15;	6,7,10,11,14,15.

The derived design is a triple system with v = 0, b = 24, $r=8, k=3, \lambda=2.$

We shall now prove that in a symmetrical design every block different from the first block has exactly λ varieties in common with the first block. Let a_i be the number of varieties common to the first block and the ith block $i=2,\cdots,b$. Then

(9.22)
$$\sum_{i} a_{i} = k(r-1)$$

since each of the k varieties of the first block occurs r times in the remaining blocks. Also

(9.23)
$$\sum_{i} \frac{a_{i}(a_{i}-1)}{2} = (\lambda - 1) \frac{k(k-1)}{2}$$

since each of the [k(k-1)]/2 prigarof varieties of the first block occurs (λ - My times in the remaining blocks. From 9.22 and 9.23 we get

$$\sum_{i} a_{i}^{2} - 2\lambda \sum_{i} a_{i} + (b-1)\lambda^{2}$$

$$= (\lambda - 1)k(k - 1) - (2\lambda - 1)k(r - 1) + (b - 1)\lambda^{2},$$

$$v, k = r, k(r - 1)$$

but b = v, k = r, $k(r - 1) = \lambda(v - 1)$ by 7.13 and therefore

$$\sum_{i} (a_i - \lambda)^2 = -\lambda k(k - 1) \text{ by 7.13 and then}$$

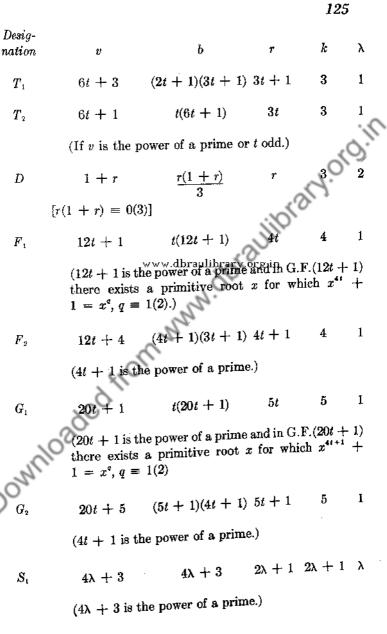

$$\sum_{i} (a_i - \lambda)^2 = -\lambda k(k - 1) + \lambda \cdot \lambda(v - 1) = 0.$$

Hence

$$a_i = \lambda$$

We finally observe that from every incomplete balanced block design B_1 , ..., B_k another incomplete balanced block design B'_1 , ..., B'_6 can be obtained by putting into B'_6 all varieties not in B_i . The parameters of this complementary design are: v, b, b-r, v-k, $b-2r+\lambda$.

R. C. Bose's two theorems yield the following series of designs. Those derivable from them by derivation and residuation

 T_1

 T_{2}

 S_{\bullet} $2n(2n\lambda + 1)$ $2n(2n\lambda + 1)$

(v is the power of a prime p, x^{2n} q_i is a full residue system mod n_i and the differences arising from n_1 , ..., $n_n \mod p$ are symmetrically repeated each occurring once.)

www.dbraulibrary.org.in

 B_1 $2\lambda + 2$

A few designs in some of these series can also be constructed by means of finite geometries. For the details of the construction the reader is referred to R. C. Bose's original paper.

The series T_1 and T_2 do not, because of the restrictions on T_1 and T_2 , contain all possible triple systems satisfying 7.12 and 7.13 although it is known that all can be constructed. However they contain all triple systems within that range of rthat has so far been found useful in the design of experiments. The series D contains all possible triple systems with $\lambda = 2$. R. C. Bose made their construction dependent on the solution of two auxiliary problems, which were later solved by Bhattacharya. (Sankhya V.6 pp. 313-314). The series S_1 , S_1' , S_n and some of the other designs yield further designs by residuation and derivation. Although many of the designs constructed by R. C. Bose had been previously obtained by other methods, some of them were constructed by him for the first time. All the designs with $r \leq 10$ known up to 1943 are tabulated in Fisher and Yates' Statistical Tables. In these tables 12 blanks were still left, namely the following:

Number*	v	b	r	\boldsymbol{k}	λ

\S1	51	85	10	6	1	

The impossibility of designs 8, 10, 14 has since been demonstrated by R. K. Nandi and Q. M. Husain in several papers which appeared in the 1946 issues of Sankhya.* The designs 17, 20, 26, 27 were constructed by Bhattacharya. (Sankhya V 7 pp. 423-424). The last two as follows:

^{*}Reference Number in Fisher and Yates Tables.

^{*}In a forthcoming paper to appear in the Canad. J. of Math. Chowla and Ryser prove that a symmetrical design with even v is impossible unless $k-\lambda$ is a square. This shows that also the design 30 is impossible.

The design (31, 31, 10, 10, 3) can be obtained from the blocks:

$$B_0 = (1_1, 2_1, 4_1, 1_2, 2_1, 4_2, 1_3, 2_3, 1_3, 0_4),$$

$$B_1 = (1_1, 6_1, 2_2, 5_2, 3_3, 4_3, 3_4, 5_4, 6_1, \infty_1),$$

$$B_2 = (\mathbf{2}_1 \; , \; \mathbf{5}_1 \; , \; \mathbf{3}_2 \; , \; \mathbf{4}_2 \; , \; \mathbf{1}_3 \; , \; \mathbf{6}_3 \; , \; \mathbf{3}_4 \; , \; \mathbf{5}_3 \; , \; \mathbf{6}_4 \; , \; \mathbf{\infty}_2),$$

$$B_3 = (3_1, 4_1, 1_2, 6_2, 2_3, 5_3, 3_4, 5_4, 6_1, 6_2)$$

by forming the blocks B_{is} mod 7 and then adjoining the blocks

$$B_1' = (0_1, 1_1, 2_1, 3_1, 4_1, 5_1, 6_1, \infty_1, \infty_2, \infty_3),$$

$$B_2' = (0_2, 1_2, 2_2, 3_2, 4_2, 5_2 \text{in } 6_2, \infty_1, \infty_2, \infty_3),$$

www.dbraulibrary.drg2in 62, \infty

$$B_3' = (0_3, 1_3, 2_3, 3_3, 4_2, 5_3, 6_3, \infty_1, \infty_2, \infty_3).$$

From this design the design (21, 30, 10, 7, 3) can be obtained by residuation.

Although a great many designs are now available, necessary and sufficient conditions for the existence of an incomplete balanced block design with given parameters v, b, r, k, λ are not known. Equations 7.12 and 7.13 are necessary conditions. The inequality 7.14 must also hold if v > k. We shall prove it now. The inequality $b \ge v$ is, because of 7.12, equivalent to $r \ge k$. We number the blocks and consider the number a.

of elements common to the first and the *i*th block.

From 9.22 and 9.23 it follows that

$$\sum_{i} a_i^2 = k([\lambda - 1]k + r - \lambda).$$

From 9.22 it also follows that k(r-1)/(b-1) is the mean of the variable a_i and therefore

$$(9.24) \sum_{i} a_{i}^{2} \ge \frac{k^{2}(r-1)^{2}}{b-1}, (\lambda-1)k+(r-\lambda) \ge \frac{k(r-1)^{2}}{b-1}$$

From 7.13 we have $(r - \lambda) = rk - \lambda v$ and this substituted in 9.24 yields

$$(9.25) k(r-1) - \frac{k(r-1)^2}{b-1} \ge \lambda(v-k)$$

 and

$$(9.26) k(r-1)\frac{(b-r)}{b-1} \ge \lambda(v-k).$$

From 7.12 we have

$$\frac{b-r}{v-k} = \frac{r}{k} .$$

ibrary.org.ir Since v - k > 0 we may divide 9.26 by v - k and obtain on account of 9.27 www.dbraulibrary.org.in

$$(9.30) r(r-1) \ge \lambda(b-1).$$

$$(9.31) r(r-k) \ge \lambda(b-v),$$

(9.30)
$$r(r-1) \geq \lambda(b-1).$$
Subtracting from this 7.13 yields
$$(9.31) \qquad r(r-k) \geq \lambda(b-v),$$
but $(b-v)/v = (r-k)/k$ by 7.12 and therefore
$$(9.32) \qquad r(r-k) \geq \frac{\lambda v}{k} (r-k),$$

$$(9.33) \qquad (r-k)(kr-\lambda v) \geq 0.$$

$$(9.33) (r-k)(kr-\lambda v) \geq 0.$$

Since $kr - \lambda v = r - \lambda > 0$ it follows that $r \ge k$.

Non-orthogonal Data

THE r-WAY CLASSIFICATION design with an equal number of replications in every subclass is the best available design for investigating the effect of classifications. However, it is not always possible to keep the numbers in the subclasses equal Suppose for instance that we wish to measure the variation in the weights of pigs at birth according to sex and litter. It is of course not possible to prescribe the litter size and the number of males in a litter. Thus we obtain a two way classification design with unequal numbers in the subclasses. Such incomplete data may also result from the fact that originally a complete layout, say aw Lathras duare was planned, but one or more experiments miscarried so that some observations are missing. Such data can also be analyzed with the help of the likelihood ratio principle but the computations are much more laborious than those described in the preceding chapters.

The solution of all problems of this kind requires, as shown in Chapter IV, the finding of Q_a and $Q_r - Q_a$. That is to say we have to minimize a quadratic form

(10.1)
$$Q = \sum_{\alpha=1}^{N} \left(y_{\alpha} - \sum_{i=1}^{k} \beta_{i} x_{i\alpha} \right)^{2}.$$

(10.2)
$$\sum_{i=1}^{k} c_{ui}\beta_i = 0 \qquad u = 1, \dots, r < k \qquad \text{rank } (c_{ui}) = r.$$
The minimum of $C = 0$

The minimum of Q with respect to the β , is denoted by Q_a if 10.2 denotes the restrictions imposed by the assumptions and Q, if 10.2 denotes the restrictions imposed by assumption and

We shall prove the following theorem.

Theorem 10.1: Let S be the minimum of Q with respect to the β_n under the restrictions 10.2. Let

$$a_{pq} = \sum_{\alpha=1}^{N} x_{p\alpha} x_{q\alpha}$$
 for $k \geq p > 0$, $k \geq q > 0$.

(10.3)
$$a_{c0} = a_{0c} = \sum_{\alpha=1}^{N} y_{\alpha} x_{q\alpha} ,$$
$$a_{0e} = \sum_{\alpha=1}^{N} y_{\alpha}^{2} .$$

Then

$$S = \frac{\Delta}{\Delta_{00}} .$$

where

and Δ_{00} is the minor of a_{00} in (Δ)

Applying the method of Lagrange operators we have

(10.6)
$$\left(\frac{\partial Q}{\partial \beta_{\nu}}\right)_{\beta_{q} = \hat{\beta}_{q}} + \sum_{\nu=1}^{r} \lambda_{\nu} c_{\nu\nu}$$

$$= 2\left(-a_{0p} + \sum_{q=1}^{k} a_{pq} \hat{\beta}_{q}\right) + \sum_{\nu=1}^{r} \lambda_{\nu} c_{\nu\nu}$$

$$= 0, \qquad p = 1, \dots, k,$$

$$= 0, \qquad \text{tikelihood estimates.}$$

where as usual the caret denotes maximum likelihood estimates.

132

We multiply the pth equation by \hat{eta}_p and sum over p. Since $\sum_{\mathbf{p}} c_{\mathbf{u}\mathbf{p}} \, \hat{\beta}_{\mathbf{p}} = 0 \text{ this yields}$ (10.7)

(10.7)
$$= \sum_{p} a_{0p} \hat{\beta}_{p} + \sum_{p} \sum_{q} a_{pq} \hat{\beta}_{p} \hat{\beta}_{q}$$
We now see

We now expand S and obtain

(10.8)
$$S = a_{00} - 2 \sum_{p=1}^{k} a_{0p} \hat{\beta}_p + \sum_{p} \sum_{q} a_{pp} \hat{\beta}_{q}$$
$$= a_{00} - \sum_{p} \hat{\alpha}_{p} \hat{\beta}_{p}$$

 $= a_{00} - \sum_{n} a_{0\nu} \hat{\beta}_{\nu}$.

Hence we obtain the following system of
$$k+r+1$$
 equations for the $k+r+1$ quantities $\hat{\beta}_0=1, \hat{\beta}_1, \dots, \hat{\beta}_k, \lambda_1/2, \dots \lambda_r/2$

$$(S-a_{00})\hat{\beta}_0+\sum_{a_{0p}}\hat{\beta}_p=0,$$
www.dbraulibrary.org.In
$$(10.9) -a_{0p}\hat{\beta}_0+\sum_{a}a_{pq}\hat{\beta}_q+\sum_{b}\frac{\lambda_a}{2}c_{np}=0, \quad p=1,\dots,k_r$$

$$\sum_{q} c_{uq} \hat{\beta}_{q} + \sum_{u} \frac{\lambda_{u}}{2} c_{uu} = 0, \quad p = 1, \dots, k_{r}$$

$$\sum_{q} c_{uq} \hat{\beta}_{q} = 0, \quad u = 1, \dots, r.$$
Since $\hat{\beta}_{0} = 1$ this system 1

Since $\hat{\beta}_0 = 1$ this system has a non-trivial solution and it

follows that
$$\begin{vmatrix}
S - a_{00} & a_{01} & \cdots & a_{0k} & 0 & \cdots & 0 \\
- a_{10} & a_{11} & \cdots & a_{1k} & c_{11} & \cdots & c_{r1} \\
\vdots & \vdots & \ddots & \vdots & \ddots & \vdots \\
- a_{k0} & a_{k1} & \cdots & a_{kk} & c_{1k} & \cdots & c_{rk} \\
0 & c_{11} & \cdots & c_{1k} & 0 & \cdots & 0 \\
\vdots & \vdots & \ddots & \ddots & \vdots \\
0 & c_{r1} & \cdots & c_{rk} & 0 & \cdots & 0
\end{vmatrix}$$

It follows that

$$S\Delta_{00}-\Delta=0, \qquad S=\frac{\Delta}{\Delta_{00}}$$

In applying this result to an r-way classification one may use to advantage the following notation. Let

(10.10)
$$(\alpha)^{x} = 1, (\alpha)^{x(i_{1}, \dots, i_{n}; a_{i_{1}}, \dots, a_{i_{n}})} = \begin{cases} 1 & \text{if } y_{\alpha} \text{ is in the} \\ a_{i_{1}}, \dots, a_{i_{n}} \text{ class} \\ & \text{of the } i_{1}, \dots, i_{n} \end{cases}$$
classification
$$0 & \text{otherwise,}$$

where y_1, \dots, y_N are the observations. Then with $\mu(i_1, \dots, i_\alpha;$ $a_{i_1,...,a_{i_{\alpha}}}$ defined as in Chapter V we have

$$Q = \sum_{\alpha} \left(Y_{\alpha} - \bigvee_{\beta=0}^{r} \underbrace{a_{i_1} \cdots a_{i_n}}^{r} \underbrace{a_{i_1}}_{a_{i_1}} \cdots \underbrace{a_{i_n}}^{r} \right)$$

$$(10.11) \cdot (\alpha)^{x(i_1, \dots, i_{\beta}; a_{i_1}, \dots, a_{i_{\beta}})} \mu(i_1, \dots, i_{\beta}; a_{i_1}, \dots, a_{i_{\beta}})^{2}.$$

n addition to the restrictions in 5.3 there may be other restrictions imposed by the hypothesis. If Δ , Δ_{00} , Δ' , Δ'_{00} are the determinants of Theorem 10.1 under the restrictions imposed on the $\mu(i_1, \dots, i_k; a_{i_1}, \dots, a_{i_k})$ under the assumption and the hypothesis respectively and if a and h respectively are the number of independent linear restrictions, then

(10.12)
$$F = \frac{a}{h} \frac{\Delta'/\Delta'_{00} - \Delta/\Delta_{00}}{\Delta/\Delta_{00}}$$

has by Theorem 4.1 the F distribution and the test based on F is the likelihood ratio test.

Although Theorem 10.1 yields very neat mathemetical formulae the numerical evaluation of Δ and Δ_{00} , although feasible with modern computational techniques, is rather laborious. There are several cases in which the solution can better be obtained by operating directly on the least square equations.

A special case in which the least square equations can easily

be solved directly is the case of an r-way design with proportional class frequencies in the subclasses. We shall indicate the treatment in the case of a two-way design. If the class frequencies are proportional we may write the number of observations in the *i*th row and *j*th column $(i - 1, \dots, r; j = 1)$

It will be convenient to use the following definitions.

$$\overline{\mu}_{ii} = \mu_{ij} - \frac{\sum_{\epsilon} n_{\epsilon}.\mu_{\epsilon i}}{\sum_{\epsilon} n_{\epsilon}} - \frac{\sum_{m} n_{\cdot m} \mu_{im}}{\sum_{m} n_{\cdot m}} + \frac{\sum_{\epsilon} \sum_{m} n_{\epsilon}.\mu_{\epsilon}.\sum_{m} n_{\cdot m} \mu_{im}}{\sum_{m} n_{\cdot m}}$$

$$\frac{\bar{\mu}_{i}}{(10.13)} = \mu_{i} - \frac{\sum_{e} n_{e} \cdot \mu_{e}}{\sum_{e} n_{e}} + \frac{\sum_{m} n_{\cdot m} \mu_{im}}{\sum_{m} n_{\cdot m}} = \frac{\sum_{e} \sum_{m} n_{e} \cdot n_{\cdot m} \mu_{en}}{\sum_{e} n_{e} \cdot \sum_{m} n_{\cdot m}}$$

$$\frac{\bar{\mu}_{\cdot i}}{\bar{\mu}_{\cdot i}} = \mu_{\cdot i} + \frac{\sum_{e} n_{e} \cdot \mu_{e, i}}{\sum_{m} n_{\cdot e} \cdot \sum_{m} n_{\cdot m} \mu_{em}} = \frac{\sum_{e} \sum_{m} n_{e} \cdot n_{\cdot m} \mu_{em}}{\sum_{e} n_{e} \cdot \sum_{m} n_{\cdot m}}$$

$$\frac{\bar{\mu}_{\cdot i}}{\bar{\mu}_{\cdot i}} = \mu_{\cdot i} + \frac{\sum_{e} n_{e} \cdot \mu_{e, i}}{\sum_{m} n_{\cdot m} \mu_{em}} = \frac{\sum_{e} \sum_{m} n_{e} \cdot n_{\cdot m} \mu_{em}}{\sum_{e} n_{e} \cdot n_{\cdot m} \mu_{em}}$$

$$\overline{\mu}_{\cdot,i} = \mu_{\cdot,i} + \frac{\sum_{e} n_{e,\mu_{e,i}}}{\text{www.albus@dibrary.obg.in}} \sum_{m} n_{em} \mu_{\cdot,m} - \frac{\sum_{e} \sum_{m} n_{e}.n_{\cdot,m} \mu_{em}}{\sum_{e} \sum_{m} n_{\cdot,m}}$$

$$\bar{\mu} = \mu + \frac{\sum_{e} n_{e}.\mu_{e}}{\sum_{e} n_{e}} + \frac{\sum_{m} n_{\cdot m} \mu_{\cdot m}}{\sum_{m} n_{\cdot m}} + \frac{\sum_{e} \sum_{m} n_{e}.n_{\cdot m} \mu_{em}}{\sum_{e} n_{e}.\sum_{m} n_{\cdot m}},$$
where $\mu(1, 2; i, j) = \mu_{10}...\mu(1; i)$

where $\mu(1, 2; i, j) = \mu_{ij}$, $\mu(1; i) = \mu_{i}$, $\mu(2; j) = \mu_{.i}$ in 5.3. It is easily verified that with these definitions

(10.14)
$$\sum_{i} n_{i,\overline{\mu}_{i,i}} = \sum_{i} n_{\cdot i} \overline{\mu}_{i,i} = \sum_{i} n_{i,\overline{\mu}_{i,i}} = \sum_{i} n_{\cdot i} \overline{\mu}_{i,i} = 0,$$

$$\mu_{i,i} + \mu_{i,i} = 0,$$

Let
$$Y_{i,i}$$
 denote the l th observation \vec{l}_i .

Let Y denote the th observation in the ith row and jth column and put

$$\begin{split} Y_{ij} &= \frac{1}{n_{i}.n_{.j}} \sum_{i} Y_{ij1}, \quad Y_{i..} = \frac{1}{n_{i}. \sum_{i} n_{.j}} \sum_{k} \sum_{l} Y_{ikl} \\ Y_{.j.} &= \frac{1}{n_{.j} \sum_{i} n_{i.}} \sum_{k} \sum_{l} Y_{kil}, \\ Y &= \frac{1}{\sum_{i} n_{i}. \sum_{i} n_{.j}} \sum_{p} \sum_{q} \sum_{l} Y_{pql} \end{split}$$

then the assumption may be written as $E(Y_{iii}) = \mu_{ii} + \mu_{ii} + \mu_{ii} + \mu_{ii} + \overline{\mu}_{ii} + \overline{\mu}_{ii} + \overline{\mu}_{ij} + \mu$ and the least square equations easily lead to

$$\frac{\hat{\mu}_{ij}}{\bar{\mu}_{ij}} = Y_{ij} - Y_{i} - Y_{\cdot j} + Y,$$

$$\frac{\hat{\mu}_{i}}{\bar{\mu}_{i}} = Y_{i} - Y,$$

$$\frac{\hat{\mu}_{i}}{\bar{\mu}_{i}} = Y_{\cdot j} - Y,$$

$$\hat{\mu}_{ij} = Y_{\cdot j} - Y_{\cdot j}$$

$$\hat{\mu}_{ij} = Y_{\cdot j} - Y_{\cdot j}$$

Thus $Q_a = \sum_i \sum_i \sum_i (Y_{ii1} - Y_{iii})^s$. The μ_{ii} , μ_{ii} , μ_{ii} , μ_{ij} , $\mu_$

$$\mu_{ij} = \overline{\mu}_{ij} - \frac{\sum_{e} \overline{\mu}_{ei}}{r} - \frac{\sum_{m} \overline{\mu}_{im}}{k} + \frac{\sum_{e} \sum_{m} \overline{\mu}_{em}}{rk},$$

$$\mu_{i.} = \overline{\mu}_{i.} - \frac{\sum_{e} \overline{\mu}_{e.}}{r} + \frac{\sum_{m} \overline{\mu}_{im}}{k} - \frac{\sum_{e} \sum_{m} \overline{\mu}_{em}}{rk},$$

$$(10.16)$$

$$\mu_{.i} = \overline{\mu}_{.j} + \frac{\sum_{e} \overline{\mu}_{ej}}{r} - \frac{\sum_{m} \overline{\mu}_{.m}}{k} - \frac{\sum_{e} \sum_{m} \overline{\mu}_{em}}{rk},$$

$$\mu = \overline{\mu} + \frac{\sum_{e} \overline{\mu}_{e.}}{r} + \frac{\sum_{m} \overline{\mu}_{.m}}{k} + \frac{\sum_{e} \sum_{m} \overline{\mu}_{em}}{rk}.$$

The details of the derivations and the discussions of the tests of various hypotheses are left to the reader as an exercise.

Sometimes one or more experiments of a complete layout miscarry. It is then often still possible without excessive labor to solve the resulting least square equations. As an example we shall consider the case of an m sided Latin square in which only one observation is missing. We shall assume that this is the observation in the 1st row, 1st column and on the 1st variety.

We denote by Y_i , Y_i , Y_i , Y_i , the sum of all observations in the *i*th row, *i*th column, *i*th variety respectively, and by Y the sum of all observations. Let r_i , c_i , v_i , denote the least square estimates of the effects of the *i*th row, *i*th column, and *i*th variety respectively and v the least square estimate of the general mean. The least square equations resulting from 7.1 are, on account of Theorem 4.5.

Y +
$$r_1$$
 + c_1 + v_1 - $(m^2 - 1)v = 0$,
Y₁... - mr_1 + r_1 + c_1 + v_1 - $(m - 1)v = 0$,
Y₁... - mc_1 + r_1 + c_1 + v_1 - $(m - 1)v = 0$,
Y₁... - mc_1 + r_1 + r_2 + r_3 - r_4 - $r_$

From the first equation we obtain $r_1 + v_1 + c_1 = (m^2 - 1)v - Y$. Substituting this in the following 3 equations we find:

$$mr_1 = Y_1... + m(m-1)v - Y,$$
 $mc_1 = Y_{-1}... + m(m-1)v - Y,$
 $mv_1 = Y_{-1}... + m(m-1)v - Y,$

Thus $m(m^2 - 1)v - mY = Y_{1..} + Y_{.1} + Y_{.1} + Y_{.1}$

$$v = \frac{Y_{1..} + Y_{.1.} + Y_{...} + (m-3)Y}{m(m-1)(m-2)}.$$

Thus finally

$$r_{1} = \frac{(m-1)Y_{1}..+Y_{.1}.+Y_{..1}-Y}{m(m-2)},$$

$$c_{1} = \frac{Y_{1}..+(m-1)Y_{.1}.+Y_{..1}-Y}{m(m-2)},$$

$$v_{1} = \frac{Y_{1}..+Y_{.1}.+(m-1)Y_{..1}-Y}{m(m-2)}$$

and for $j \geq 2$

$$c_1 = \frac{Y_{1..} + (m-1)Y_{.1} + Y_{.1} - Y}{m(m-2)},$$

$$v_1 = \frac{Y_{1..} + Y_{.1} + (m-1)Y_{..} - Y}{m(m-2)}$$
or $j \ge 2$

$$r_j = \frac{Y_{j..}}{m} - \frac{Y_{1..} + Y_{.1} + Y_{.1} + (m-3)Y}{m(m-1)(m-2)},$$

$$c_j = \frac{Y_{.j.}}{m} - \frac{Y_{1..} + Y_{.1} + Y_{.1} + (m-3)Y}{m(m-1)(m-2)},$$

$$v_j = \frac{Y_{..j}}{m} - \frac{Y_{1..} + Y_{..} + Y_{..} + (m-3)Y}{m(m-1)(m-2)}.$$

In testing the hypothesis $v_i = 0$ $(j = 1, \dots, m)$ one obtains an analogous result for r_i and c_i . The test of the hypothesis $v_i = v_k$ is best carried out by utilizing Theorem 4.3 and its corollary. The details of the analysis are left to the reader. A detailed discussion of the analysis of Latin squares when some observations are missing is given by D. B. DeLury (Journal of the American Statistical Association, Vol. 41, pp. 370-389). A general method for the treatment of missing observations was given by F. Yates (Empire Jour. Experimental Agric., Vol. I, 1933).

Yates proceeds as follows: Suppose we have a regression equation

(10.17)
$$E(y_{\alpha}) = \sum_{i=1}^{s} g_{i\alpha}\beta_{i} \qquad \alpha = 1, \dots, n$$

and suppose further that the observations y_1 , \cdots , y_k are

missing. Differentiation of $Q = \sum_{\alpha} (y_{\alpha} - \sum_{i} g_{\alpha} \beta_{i})^{2}$ with respect to the β_{i} yields the least square equations

(10.18)
$$\sum_{\alpha} g_{i\alpha} y_{\alpha} = \sum_{i} \sum_{\alpha} g_{i\alpha} g_{i\alpha} \hat{\beta}_{i} \qquad (i + 1, \dots, s).$$

Differentiation of Q with respect to y_1, \dots, y_r which we also regard as unknown parameters yields the additional equations

$$(10.19) y_{\alpha} = \sum_{i=1}^{s} g_{i\alpha} \hat{\beta}_{i}, \alpha = 1, \dots, k.$$

We may first solve 10.18 for the $\hat{\beta}_i$ and then substitute the values of $\hat{\beta}_i$, so obtained into 10.19. Thus we obtain k equations for the k unknown quantities y_1, \dots, y_k and the solutions to these equations are the least square estimates of y_1, \dots, y_k . This method is not least square estimates of y_1, \dots, y_k .

This method is particularly advantageous in the case of designs where the expressions for the β_i are already known.

We shall exemplify Yates method in a Latin square with one observation missing. We obtain from 7.2 and 10.19 for the least square estimate \hat{Y}_{111} of Y_{121} .

$$\hat{Y}_{111} = \frac{3\hat{Y}_{111}}{m} + \frac{Y_{.1} + Y_{.1} + Y_{.1}}{m} - \frac{2\hat{Y}_{111}}{m^2} - \frac{2Y}{m^2},$$

$$\hat{Y}_{111} = \frac{m^2}{(m-1)(m-2)} \frac{Y_{1..} + Y_{.1.} + Y_{.1.}}{m} - \frac{2Y}{m^2}.$$

Substituting \hat{Y}_{111} for Y_{111} in 7.2 one then obtains equations for v_i , c_i , r_i . The reader may verify that these equations are the same that were previously derived by a direct application of the maximum likelihood principle.

CHAPTER XI

Factorial Experiments

IT WILL BE CONVENIENT in this as in the previous chapters to use the picture of an agricultural field experiment. This is done to give the reader a concrete picture but should not be taken to imply that the use of the designs presented is restricted to agricultural experimentation.

Suppose that the influence of m factors, say m different fertilizers, on the yield of wheat is to be tested. Each of these factors may be applied on different levels. Let the *i*th factor be applied on t_i levels, so that all in all $t_1t_2 \cdots t_m$ treatment combinations are possible

combinations are possible www.dbraubbrary.org in the *i*th class If we consider the *i*th level of the α th factor is the *i*th class of the α th classification in an m way classification design, we can use the methods of analysis of Chapter V. The estimates of the main effects and interactions $A(1, \dots, \alpha; a_1, \dots, a_n)$ appearing in 5.5 are linear forms of the observations of the form

form
$$(11.1) \quad \sum_{b_1} \cdots \sum_{b_n} l_{b_1, \dots, b_n} x(1, \dots, \alpha; b_1, \dots, b_n),$$

where $x(1, \dots, \alpha; b_1, \dots, b_{\alpha})$ is defined as in Chapter 5. We preced to compute the coefficient of $x(1, \dots, s, s+1, \dots, \alpha; a_1, \dots, a_s, b_{s+1}, \dots, b_{\alpha})(b_i \neq a_i)$ in $A(1, \dots, \alpha; a_1, \dots, a_{\alpha})$. This term occurs as a summand in all $x(k_1, \dots, k_{\beta}; a_{k_1}, \dots, a_{k_{\beta}})$ where $k_1 \dots, k_{\beta}$ is a combination out of 1, k_{β} ; a_{k_1} , a_{k_2} , a_{k_3} , $a_$

$$\sum_{1,\dots,s} \sum_{\beta=0}^{s} (-1)^{\alpha-\beta} \frac{t_{k_1} \cdots t_{k_\beta}}{t_1 \cdots t_{\alpha}}.$$

Thus

$$\sum_{e_{a+1}} l_{a_1, \dots, a_1 e_{a+1} b_{a+1}, \dots, b_n}$$

(11.2)
$$= \left(\sum_{1,\dots,s} \sum_{\beta=0}^{s} (-1)^{\alpha-\beta} \frac{t_{i_1} \dots t_{i_s}}{t_{i_1} \dots t_{i_s}} \right) (t_{s+1} - 1)$$

$$+\sum_{1,\dots,s+1}\sum_{p=1}^{s+1}\left(-1\right)^{n-p}\frac{t_{q_{p}}\cdots t_{q}}{t_{1}\cdots t_{q}}$$

 $+\sum_{1,\dots,n+1}\sum_{g=1}^{r+1}(-1)^{\frac{r-g}{2}}\frac{t_{g}\dots t_{g}}{t_{1}\dots t_{g}}.$ By splitting the second term on the right side of 11.2 into terms for which $k_{\theta} = s + 1$ and terms for which $k_{\theta} < s + 1$ one obtains $\sum_{a_{i+1}} l_{a_{i}...a_{i}c_{i+1}b_{i+1}...b_{a}} = 0$. Similarly one proves that the coefficients $l_b,...,b_a$ appearing in 11.4 satisfy the equation

(11.3)
$$\sum_{\text{wwwidbraulibrary.org.in}} l_{b_1, \dots, b_n} = 0 \\ \text{org.in} i = 1, \dots, \alpha.$$

We generalize the concept of interaction and define: Any linear form

(11.4)
$$L = \sum_{a_1} \cdots \sum_{a_n} l_{a_1, \dots, a_n} x(i_1, \dots, i_n; a_1, \dots, a_n)$$

which is not identically 0 will be termed a component of the interaction between the factors i_1 , \cdots , i_a if

(11.5)
$$\sum_{\alpha_i} l_{\alpha_1, \dots, \alpha_n} = 0 \qquad i = 1, \dots, \alpha$$

for all choices $a_1 \cdots a_{i-1} a_{i+1} \cdots a_{\alpha}$.

Two linear forms

$$\sum_{k=1}^{n} a_k x_k \quad \text{and} \quad \sum_{j=1}^{n} b_j x_j$$

are called orthogonal if

(11.6)
$$\sum_{k=1}^{n} a_k b_k = 0.$$

THEOREM 11.1: Two interaction components G and H belonging to two different sets of factors are orthogonal.

We may always arrange the notation so that G is a component of the interaction of the factors 1, 2, \cdots , u and Hof the factors $p, p + 1, \dots, v$ where p > 1. Let

of the factors
$$p, p + 1, \dots, p$$
 where $p > 1$.
$$G = \sum_{\alpha} l_{\alpha} x_{\alpha} = \sum_{\alpha_{1}} \dots \sum_{\alpha_{n}} l_{\alpha_{1}, \dots, \alpha_{n}} x(1, \dots, u; a_{1}, \dots, a_{n}),$$

$$H = \sum_{\alpha} i_{\alpha}^* x_{\alpha} = \sum_{a_p} \cdots \sum_{a_r} l_{a_r, \dots, a_r} x(p, \dots, v; a_p, \dots, a_r).$$

If $x_{\alpha} = x_{a_1 \cdots a_m}$ then $l_{\alpha} = l_{a_1 \cdots a_n}/t_{n+1} \cdots t_m$. Thus writing $w = \max(u, v)$

$$w = \max (u, v)$$

$$(11.7) \qquad \sum_{\alpha} l_{\alpha} l_{\alpha}^{*} = \frac{(t_{1} \cdots t_{u})(t_{p} \cdots t_{v})(t_{w+1} \cdots t_{m})}{(t_{1} \cdots t_{m})^{2}}$$

$$\sum_{\substack{a_1\\ w \text{ w. w.}}} \dots \sum_{\substack{a_n\\ a_n}} \sum_{\substack{a_1\\ a_1, \dots, a_n\\ a_n}} l_{a_1, \dots, a_n} l_{a_n, \dots, a_n} = 0$$

by 11.5.

Lemma 11.1: If L_1 , \cdots , L_i are orthogonal to L then $\sum_i \lambda_i L_i$ is orthogonal to L for all values λ_1 , \cdots , λ_s .

The proof of Lemma II.1 is left to the reader.

Solving the equations 11.5 we may choose arbitrarily the quantities $l_{a_i...a_{\alpha}}$ for $a_i \leq t_i - 1$. The equations 11.5 can then be satisfied by putting successively

$$l_{t_1 a_2, \dots, a_{\alpha}} = -\sum_{a_1=1}^{t_1-1} l_{a_1 a_2, \dots, a_{\alpha}}, \quad a_2 < t_2, \dots, a_{\alpha} < t_{\alpha},$$

$$l_{a_1 i_2, \dots, a_n} = -\sum_{a_2=1}^{t_1-1} l_{a_1 a_2, \dots, a_n}, \quad a_3 < t_3, \dots, a_n < t_\alpha,$$

$$l_{a_1, \dots, a_{n-1} l_n} = - \sum_{a_n=1}^{t_n-1} l_{a_1 a_2, \dots, a_n}$$

Thus the equations 11.5 have exactly $(t_1 - 1) \cdots (t_a - 1)$ independent solutions. That means that every solution of 11.5 can be expressed as a linear combination of any $(t_1-1)\cdots(t_\alpha-1)$ linearly independent solutions. By the method used in the proof of lemma 4.1 we can therefore find a system S of $(t_1-1)\cdots(t_\alpha-1)$ normalized orthogonal linear forms such that every form in S is a component of the interaction between the factors i_1,\cdots,i_α and such that every component of such an interaction is a linear combination of forms in the system S.

The interaction components of different factors are orthogonal to each other and hence linearly independent. Thus together with the mean we obtain

$$1 + \sum_{k=1}^{m} \sum_{1, \dots, m} (t_{i_1} - 1) \cdots (t_{i_k} - 1) = t_1 t_2, \dots, t_m$$

independent linear forms any breakferefore any linear function of the observations may be expressed as a linear combination of the mean and any set of $(t_1 \cdots t_m) - 1$ linearly independent interactions.

In considering the analysis of factorial designs we may therefore consider the following general problem. Given n normally distributed random variables x_1, \dots, x_n all with the same variance but different means. We know that certain linear forms in x_1, \dots, x_n

(11.8)
$$L_{i} = \sum_{i=1}^{n} a_{ii} x_{i} \qquad i = 1, \dots, s$$

have the mean value 0. We wish to test, whether certain other forms

(11.9)
$$L_{i} = \sum_{i=1}^{n} a_{ii} x_{i} \qquad i = s+1, \dots, r$$

also have mean value 0.

In the first place we may eliminate, from the assumption and hypothesis successively, forms such that L_1 , ..., L_s , may be assumed to be independent. Next we may orthogonalize and normalize the assumption and hy-

pothesis by the method used in the proof of lemma 4.1. We may then add n - r linear forms

$$\bar{L}_i = \sum_{i=1}^n \hat{a}_{ii} x_i \qquad i = r+1, \cdots, n.$$

such that the matrix

$$\begin{pmatrix} a_{11} & \cdots & a_{1n} \\ \vdots & & \vdots \\ \vdots & & \vdots \\ a_{n1} & \cdots & a_{nn} \end{pmatrix}$$

is orthogonal. Then

$$Q = \sum_{i=1}^{n} (x_i - E(x_i))^2 = \sum_{www.dbrawkibrary.org.in}^{n} (L_i - E(L_i))^2$$

such that the matrix
$$\begin{pmatrix} a_{11} \cdots a_{1n} \\ \vdots \\ \vdots \\ a_{n1} \cdots a_{nn} \end{pmatrix}$$
 is orthogonal. Then
$$Q = \sum_{i=1}^n \left(x_i - E(x_i) \right)^2 = \sum_{w \in \mathcal{W}}^n (L_i - E(L_i))^2$$
 Thus
$$Q_a = \sum_{i=1}^r L_i^2, \ Q_r - Q_a = \sum_{i=s+1}^r L_i^2 \ \text{and} \ F = \frac{s}{r-s} \frac{Q_r - Q_a}{Q_a}$$
 is the likelihood ratio statistic for testing the hypothesis
$$E(L_i) = 0 \\ (a_i - s_i) + 1 \\ (a_i -$$

is the likelihood ratio statistic for testing the hypothesis $E(L_i) = 0 (i = s + 1, \dots, r)$ under the assumption $E(L_i) = 0$, $(i = 1, \dots, s)$

In the analysis of factorial experiments we shall always put

$$L_1 = \frac{x_1 + \cdots + x_n}{n^{1/2}}$$

so that the sum of the coefficients of L_2 , \cdots , L_n is 0 because of the orthogonality.

We then consider the mean yield $E(x_i)$ as composed of the treatment effect T_i and the block effect b_a due to the soil fertility of the α th block. The experiment is replicated in hdifferent blocks each containing a complete replication of all treatments. We shall denote by x_i^{α} the value observed under the *i*th treatment in the α th block and put $L_i^a =$ $L_i(x_1^{\alpha}, \dots, x_n^{\alpha})$. Then since $L_i^{\alpha} = (x_1^{\alpha} + \dots + x_n^{\alpha})/n^{1/2}$ we see that $E(L_i^{\alpha}) = L_i(T_1, \dots, T_n) \equiv S_i$ for $i = 2, \dots, n$ and $\underline{E}(L_1^a) = L_1(T_1, \dots, T_n) + n^{1/2} b_n - S_1 + n^{1/2} b_a$ Let \overline{L}_i be the mean of all L_i^a then

$$Q = \sum_{\alpha=1}^{h} \sum_{i=1}^{n} (x_i^{\alpha} - T_i - b_{\alpha})^2$$

$$= \sum_{\alpha=1}^{h} \sum_{i=2}^{n} (L_i^{\alpha} - \overline{L}_i)^2 + h \sum_{i=2}^{n} (\overline{L}_i - S_i)^2$$

$$+ \sum_{\alpha=1}^{h} (L_1^{\alpha} - S_1 - u^{1/2}b_{\alpha})^2.$$

If we now test the hypothesis $S_{k+1} = \cdots = S_{k+n} = 0$ under the assumption $S_2 = \cdots = S_k = 0$ then

$$Q_{a} = \sum_{\text{www.dbraulibrary.org.In}}^{h} \sum_{i=1}^{h} (L_{i}^{a} - \overline{L}_{i})^{2} + h \sum_{i=2}^{h} \overline{L}_{i}^{2},$$

$$Q_r - Q_a = h \sum_{i=k+1}^{k+u} \overline{L}_i^2$$
.

Thus Q_a has (k-1) + (h-1)(n-1) degrees of freedom and $Q_r - Q_a$ has u degrees of freedom. Note that more than one replication is needed unless certain of the S_i are known

We recall that one of the necessary assumptions of the analysis was the uniformity of the soil. If the number of treatment combinations is large then the blocks become too large to make this assumption. In this case one conducts the experiment in several blocks containing among themselves a complete replication and resorts to the technique of confounding linear forms of the treatment effects in which one is not

A linear form

$$S = \sum_{i=1}^{n} a_i T_i$$

will be called confounded in the block B_a if $a_i = c_a$ whenever T_{c} is the effect of a treatment applied in the $lpha ext{th}$ block B_{a} . A

linear form S will be called orthogonal to B_a if $\sum_{T_i \in B_a} a_i = 0$. A linear form $S = \sum_i a_i T_i$ is called normalized if $\sum_i a_i^2 = 1$.

Lemma 11.2: If S_1 , \cdots , S_n are confounded in the block B then any linear function $S=\lambda_1S_1+\cdots+\lambda_nS_r$ is also confounded in E.

The proof of Lemma 11.2 is left to the reader.

Lemma 11.3: If L_1 , ..., L_n are n orthogonal functions of the variables x_1 , ..., x_n and L is orthogonal to L_1 then

$$11.10 L = a_2L_2 + \cdots + a_nL_n.$$

Proof: Since L_1 , ..., L_n are independent we certainly have $L = a_1 L_1 + \cdots + a_n L_n$. Let $L = \sum_i \lambda_i x_i$, $L_k = \sum_i \lambda_k x_i$ then $\sum_i \lambda_i \lambda_{ni} = \sum_k a_k \sum_i \lambda_{ki} \lambda_{ni} = a_n \sum_i \lambda_{ni}^2$. Thus

then
$$\sum_{i} \lambda_{i} \lambda_{ui} = \sum_{k} a_{k} \sum_{i} \lambda_{ki} \lambda_{ui}$$
 www.dbrauhibrary.org.in
$$a_{u} = \frac{\sum_{i} \lambda_{i} \lambda_{ui}}{\sum_{i} \lambda_{ui}}$$
(11.11)

Since L is orthogonal to L_1 we must have $a_1 = 0$.

Theorem 11.2: If S_1 , S_2 , ..., S_n is a system of orthogonal linear forms in the treatment effects T_1 , ..., T_n and S_1 , S_2 , linear forms in the treatment effects B_1 , ..., B_n consisting of ..., S_n are complete replication of the treatments, then S_{n+1} , ..., S_n are orthogonal to these blocks.

Proof: Let S_i' $(i=1\cdots v)$ be the sum of the treatment effects of all the treatments in the ith block then S_1 , \cdots , S_n are linear functions of S_1' , \cdots , S_n' . However since S_1 , \cdots , S_n are independent we may express S_1' , \cdots , S_n' also by \cdots , S_n are independent we may express S_1' , \cdots , S_n' are orthogonal to S_{n+1} , \cdots , S_n .

onal to S_{v+1} , ..., S_n .

Suppose now that we are interested in certain linear functions

Suppose now that we are interested in certain linear functions S_{v+1} , ..., S_{v+k} of the treatment effects T_1 , ..., T_n , $n = u \cdot v$, S_{v+1} , ..., S_{v+k} of the treatment in v blocks of u treatments and wish to arrange our experiment in v blocks of u treatments and wish to arrange our experiment in v blocks of u treatments and wish to arrange our experiment in v blocks of u treatments and wish to arrange our experiment in v blocks of u treatments and wish to arrange our experiment in v blocks of u treatments and wish to arrange our experiment in v blocks of u treatments and wish to arrange our experiment in v blocks of u treatments and wish to arrange our experiment in v blocks of u treatments and wish to arrange our experiment in v blocks of u treatments and wish to arrange our experiment in v blocks of u treatments and wish to arrange our experiment in v blocks of u treatments and wish to arrange our experiment in v blocks of u treatments and wish to arrange our experiment in v blocks of u treatments and v or thought v and v or v

onal forms. Suppose that we can find an arrangement of the treatments in v blocks such that S_1 , ..., S_n are confounded in all the blocks. Then S_{n+1} , ..., S_n will be orthogonal to all the blocks by Theorem 11.2.

Let y_{α} denote the yield of the α th plot and consider

(11.12)
$$Q = \sum_{\alpha=1}^{n} (y_{\alpha} - T_{\alpha} + b_{\epsilon_{\alpha}})^{2},$$

where T_{α} is the effect of the treatment applied to the α th plot and $b_{i_{\alpha}}$ is the effect of the block in which the α th plot lies. Let $S_{\alpha} = \sum_{\beta} t_{\alpha\beta} T_{\beta}$ and put $L_{\alpha} = \sum_{\beta} t_{\alpha\beta} y_{\beta}$. Then

(11.13)
$$Q = \sum_{\alpha} (L_{\alpha} - S_{\alpha} - \sum_{\beta} t_{\alpha\beta} b_{\beta\beta})^{2}.$$

If L_{α} is orthogonal to all the blocks then $\sum_{\beta} t_{\alpha\beta}b_{i\beta} = \sum_{i} b_{i} \sum_{\nu\beta \in A_{\beta}} \int_{\partial a} b \bar{t}_{\alpha} db \bar{t}_{$

(11.14)
$$\sum_{\beta} t_{\alpha\beta} b_{i\beta} = u \sum_{i} c_{\alpha i} b_{i}.$$

But the linear forms L_1 , \cdots , L_s are orthogonal and therefore the matrix $(c_{\alpha i})$ is an orthogonal matrix and hence non-singular. We can therefore always solve the system of equations

$$L_{\alpha} - S_{\alpha} = u \sum_{i} c_{\alpha i} b_{i}$$
 $\alpha = 1, \dots, v$

whatever the value of S_{α} . Thus in minimizing Q under certain assumptions on S_{z+1} , \cdots , S_{z+k} with respect to the S_{α} and b_i we may always choose the b_i so that the first v terms of 11.13 vanish. We therefore need only minimize

(H.15)
$$Q' = \sum_{\alpha=\nu+1}^{n} (L_{\alpha} - S_{\alpha})^{2}.$$

The same argument also applies if the experiment is replicated several times. We shall formulate this result as

Theorem 11.3: Let x_1, \dots, x_u , be uv observations from v different blocks B_1, \dots, B_v of u observations each obtained in applying the treatments T_1, \dots, T_u , respectively. Let S_1, \dots, T_u

 $S_{\mu\nu}$ be uv normalized orthogonal forms $S_{\alpha} = \sum_{\beta} t_{\alpha\beta} T_{\beta}$ in the treatment effects T_1 , \cdots , T_{uv} and assume that S_1 , \cdots , S_r are confounded in all blocks.

If the hypothesis $S_{\alpha}=0,\, \alpha=v+k+1,\, \cdots, v+k+s$ is tested under the assumption $S_{\alpha}=0, \ \alpha=v+1, \cdots, v+k$, $E(x_a) = T_a + b_{ia}$, then

$$Q_a = \sum_{r+1}^{c+k} L_{\alpha}^2, \qquad Q_r - Q_a = \sum_{r+k+1}^{c+k+s} L_{\alpha}^2,$$

where

$$L_{\alpha} = \sum_{\beta} t_{\alpha\beta} x_{\beta} .$$

If the experiment is replicated r times and \mathbf{L}_a , is the value of , in the ith replication then L_a in the ith replication then

Under the interpolation then
$$Q_{a} = r \sum_{\alpha=v+1}^{v+k} \overline{L}_{\alpha}^{2} + \sum_{\alpha=v+1}^{www.dbrautibrary.org.} (L_{\alpha i}^{2} - L_{\alpha}^{2})^{2},$$

$$Q_{r} - Q_{a} = r \sum_{v+k+1}^{v+k+v} \overline{L}_{\alpha}^{2},$$
where
$$\overline{L}_{\alpha} = \frac{1}{r} \sum_{i=1}^{r} L_{\alpha i}.$$

where

$$\overline{L}_a = \frac{1}{r} \sum_{i=1}^r L_{ai} .$$

Thus if we are interested in the linear forms S_{i+1} , ..., S_{i+k} and wish to arrange the treatments T_i , \cdots , T_u , into vblocks we have to find v linear forms S_1 , ..., S_v orthogonal to S_{z+1} , ..., S_{z+k} and a design with v blocks where S_1 , ..., S, are confounded in all the blocks. Since the mean is always confounded this can only be possible if S_{s+1} , ..., S_{s+k} are orthogonal to the mean, that is to say if the sum of the coefficients of S_{v+1} , ..., S_{v+k} vanishes.

In the case of a factorial experiment the method of attack is as follows. If $S_{\alpha} = \sum_{\beta} t_{\alpha\beta} T_{\beta}$ then we first form the linear forms $L_{\alpha} = \sum_{\beta} \tilde{t}_{\alpha\beta} x_{\beta}$. Let I_{1}, \dots, I_{u} , be a complete normalized system of interaction components as constructed at the beginning of this chapter. Then

$$(11.17) \quad L_{\alpha} = \sum_{\beta} u_{\alpha\beta} I_{\beta} \qquad \alpha = v + 1, \dots, v + k$$

with certain values of the $u_{\alpha\beta}$. If it is possible to confound v interaction components which have the coefficient 0 in all equations of the system 11.17, then L_{α} and thus also S_{α} ($\alpha = v + 1, \dots, v + k$) will be orthogonal to all the blocks by Theorem 11.2. The L_{α} are by Theorem 11.1 and Lemma 11.1 orthogonal to all the components say I_1, \dots, I_s of Interactions which do not enter in 11.17. The L_{α} may then be orthogonalized and normalized so that Theorem 11.3 applies. If the experiment is replicated we may have to add some functions of the interaction components $I_{\alpha\beta}$, ..., $I_{\alpha\beta}$ to obtain a complete normalized orthogonal system.

The linear forms of interest to the experimenter are usually the main effects and lathrater organizations themselves or linear combinations of them. Thus it is important to construct designs where only interactions of order 2 or higher are confounded. The problem of constructing such designs when all factors are at two or three levels respectively was solved by F. Yates (The Design and Analysis of Factorial Experiments, Technical Communication No. 35, Imperial Bureau of Soil Science). Yates' publication contains also many examples and presents in detail efficient methods of computation applicable to factorial designs. The more general problem of confounding only interactions of order 2 or higher in designs where each factor is at s levels and s is the power of a prime p was first solved by R. A. Fisher (Ann. of Eugenies (1945) 12, pp. 376-381). An alternative method has been given by Radhakrishna Rao (Sankhya 11 pp. 67-78). In the following we shall present

Let $\alpha_0 = 0$, $\alpha_1 = 1$, α_2 , \dots , α_{s-1} be the elements of G.F.(s). Denote the levels of the factors by α_0 , \dots , α_{s-1} and let $y(\alpha_{i_1} \cdots \alpha_{i_m})$ be the observations with the first factor at the α_i , st level, the 2nd factor at the α_i , nd level and so on. Consider then for every α_i the set of observations $y_{z_1 \dots z_m}$ where x_{i_1}, \dots, x_{i_k} satisfy the equation

(11.18)
$$b_1 x_{i_1} + \cdots + b_k x_{i_k} = \alpha_i,$$
$$j = 0, \cdots, s - 1, b_1 \neq 0, \cdots, b_k \neq 0.$$

Corresponding to the s different values of α_i we obtain s sets of observations M_1 , \cdots , M_s and each observation is contained in exactly one of the M_i . Consider now any orthogonal matrix $\lambda_{ij}(i,j=1,\cdots,s)$ whose first row is $(s^{-1/2},\cdots,s^{-1/2})$. Let T_1 , \cdots , T_s stand for the sum of all observations $y_{z_1\cdots z_m}$ whose indices satisfy the equation 11.18 with $j=0,\cdots$, s-1 respectively and consider the expressions

whose hattes satisfy the equation
$$i = 1$$
 respectively and consider the expressions (11.19) $L_i = \sum_{j=1}^s \lambda_{ij} T_i \quad i = 1, \dots, s$.

We shall prove that L_2, \dots, L_s are all components of

We shall prove that L_2 , \cdots , L_s are all components of the interaction between the factors brautibrary i of All observations with any fixed values x_i , \dots , x_i , must lie in T_i if one of them does. Hence $L_i = \sum_i \lambda_{ij} T_i$ are linear forms in the means $y(i_1, \dots, i_k; x_{i_1}, \dots, x_{i_k})$. Keeping now x_{i_1}, \dots, x_{i_k} fixed and summing over the coefficients of $y(i_1, \dots, i_k; x_i, \dots, x_{i_k})$ with respect to x_{i_1} we obtain $\sum_i \lambda_{ij}$ because if x_{i_1} takes all values α_0 , \cdots , α_{s-1} then α_i in 11.18 takes all values in G.F.(s). Since $\sum_{i} \lambda_{ij} = 0$ for $i = 2, \dots, s, 11.5$ is fulfilled and the L_{i} i > 1 in 11.19 are therefore components of the interaction between the i_1, \dots, i_k th factors. There are $(s-1)^{k-1}$ systems of coefficients b_1 , \cdots , b_k leading to different functions L_2 , \cdots , L, since σb_1 , \cdots , σb_k leads to the same functions as b_1 , ..., b_k . Thus there are $(s-1)^k$ different interaction components obtained by taking all possible values for b_1 , ..., b_k . That they are independent of each other and hence give a complete system of components of the interaction between the factors i_1 , ..., i_k will be proved by showing that two interaction components belonging to two different coefficient systems are orthogonal to each other. Consider then

$$(11.20) b_1 x_{i_1} + \cdots + b_k x_{i_k} = \alpha_i,$$

$$(11.21) c_1 x_{i_1} + \cdots + c_k x_{i_k} = \alpha_i.$$

Since the matrix

$$\begin{pmatrix} b_1 , \cdots , b_k \\ c_1 , \cdots , c_k \end{pmatrix}$$

is of rank 2 there is at least one 2 by 2 submatrix of rank 2. Suppose therefore that

$$\begin{vmatrix} b_1 & b_2 \\ c_1 & c_2 \end{vmatrix} \neq 0.$$

Then we may fix x_{i_1} , \cdots , x_{i_k} arbitrarily and this completely determines x_1 , x_2 . Hence we obtain exactly s^{k-2} points (x_1, \dots, x_k) which satisfy 11.20 and 11.21 simultaneously. Thus if T_1, \dots, T_s are the sums of all observations satisfying 11.20 for $i = 0, \dots, T_s$ are the sums of all observations satisfying defined for 11.21 and if $L_i = \sum_i \lambda_{ij} T_i = \sum_{\alpha} \lambda_{\alpha} y_{\alpha}$, $L'_i = \sum_i \lambda_{ij} U_i = \sum_{\alpha} \mu_{\alpha} y_{\alpha}$. Then since $\sum_i \lambda_{ij} = 0$ we must have

(11.22)
$$\sum_{\alpha} \lambda_{\alpha} \mu_{\alpha} = s^{k-2} \sum_{i} \sum_{l} \lambda_{il} \lambda_{ij} = 0.$$

Thus L_i is orthogonal to L_i' . We shall state this result as a theorem.

Theorem 11.4: Let (b_1, \dots, b_m) be any set of m elements of G.F.(s), not all 0, and consider the sets M_k of points (x_1, \dots, x_m) in E.G.(m, s) satisfying the equation

$$b_1x_1+\cdots+b_mx_m=\alpha_k$$

resp. where α_0 , \cdots , α_{s-1} are the marks of G.F.(s). Let (x_1, \dots, x_m) stand for the treatment combination having the α th factor at the level x_a and let (λ_{ij}) be an orthogonal $s \times s$ matrix whose first row is $(1/s^{1/2}, \dots, 1/s^{1/2})$ and let T_k be the sum of all observations y_2, \dots, y_m where (x_1, \dots, x_m) is in M_k . Then between the factors i_1, \dots, i_k if $b_{i_k} \neq 0$ ($\alpha = 1, \dots, k$) and $b_i = 0$ for $j \neq i_a$, ($\alpha = 1, \dots, k$).

The interaction component L_i will be said to correspond to the point (b_1, \dots, b_n) of P.G.(m, s). Two interaction components corresponding to different points are orthogonal.

We consider the solutions of the system

$$b_{ij}x_i + \cdots + b_{im}x_m = \alpha_{ki},$$

$$(11.23) \qquad i = 1 \cdots u < m, \quad \text{rank } (b_{ij}) = u.$$

$$x_i, b_{ij} \subset G.F.(s).$$

There are s^{m-s} solutions for x_1 , \cdots , x_m . If we solve 11.23 for all combinations $(\alpha_k, \dots, \alpha_{k_n})$ we obtain s^s sets of s^{m-s} treatment combinations each. If these are taken as the contents of s^s blocks then the set of interaction components corresponding to any linear combination $\sum_i \lambda_i(b_i, \dots, b_{im})$ will be confounded in all the blocks. The strategy by $(s_n - 1)$ sets of interaction components will be confounded giving $(s - 1)(s^s - 1)/(s - 1) = s^s - 1$ or with the mean s^s independent orthogonal functions confounded. The remaining ones are orthogonal to all the blocks by Theorem 11.2.

We wish to confound only interactions between at least 3 factors. We put u = m - t and assume that $m \le (s^t - 1)/(s-1)$. There are $(s^t - 1)/(s-1)$ linear forms in the variables x_1, \dots, x_t with coefficients in G.F.(s) independent in pairs. From these we choose m and each of these forms will now be identified with a factor. We then consider all points (x_1, \dots, x_t) where x_1, \dots, x_t are elements of G.F.(s). Let

(11.24)
$$L_i = \sum_{k=1}^t \alpha_{ik} x_k \qquad i = 1, \cdots, m$$

be the *m* linear forms chosen. In substituting the points (x_1, \dots, x_t) we obtain

(11.25)
$$\sum_{k=1}^{l} \alpha_{ik} x_k = y_i.$$

Thus we obtain a set S of s' points of E.G.(m, s). We shall show that

- 1.) S is a subspace of E.G.(m, s).
- 2.) To every pair y_i , y_i , $i, j \leq m$ there are exactly s^{t-2} points in S which contain both y, as ith coordinate and y, as jth co-

Proof of 1. Let y_1, \dots, y_m ; z_1, \dots, z_m be two points in S. Then there are two points $(x_1^{(1)}, \dots, x_i^{(1)})$ and $(z_1^{(2)}, \dots, z_i^{(2)})$ in E.G.(t, s) such that

$$\sum_{k} \alpha_{ik} x_{k}^{(1)} = \lambda y_{i} \; ; \; \sum_{k} \alpha_{ik} x_{k}^{(2)} = \mu z_{i}$$

hence

$$\sum_{k} \alpha_{ik} (x_k^{(1)} + x_k^{(2)}) = \lambda y_i + \mu z_i$$

Thus $\{\lambda y_i + \mu z_i\}$ is a point of S which proves 1.

 $\sum_{k} \alpha_{ik} x_k^{(2)} = \mu z_i$ $\sum_{k} \alpha_{ik} (x_k^{(1)} + x_k^{(2)}) = \lambda y_i + \mu z_i$ z_i is a point of S which of points in CThe number of points in S containing y_i as ith coordinate and y_i as ith Cappdinatears the innumber of solutions of the equations

$$L_i = \sum_{k=1}^t \alpha_{ik} x_k = y_i ,$$

(11.26)

$$L_i = \sum_{k=1}^i \alpha_{ik} x_k = y_i .$$

Since L_i and L_j are independent there are exactly s^{i-2} solutions.

The point $(0, 0, \dots, 0)$ is in S. Let the point (y_1, \dots, y_m) correspond to the experiment where the ith factor is on the y_i th level, where the elements of G.F.(s) are numbered in some arbitrary way. Let the blocks be constructed as follows. Take S as the initial block. To obtain the second block take any point P not in S and add it to all the points in S. We shall denote the second block by (S + P). If there is a point Q left which is neither in S nor in (S+P) form (S+Q) and continue the process until all points of F.G.(m, s) are exhausted. Since S is a subspace it follows easily that any two sets (S+P), (S+Q) are either identical or have no point in common. Thus the sets obtained by our construction have no point in common.

If the interaction components belonging to b_1, \dots, b_m are confounded in S then for all points (y_1, \dots, y_m) in S we must have, since S contains the point $(0, 0, \dots, 0)$,

$$b_1y_1+\cdots+b_my_m=0.$$

Let the element z_1, \dots, z_m be an element of (S+P) then $b_1(y_1+z_1)+\dots+b_m(y_m+z_m)=b_1z_1+\dots+b_mz_m=$ const. The confounded interactions form the space orthogonal to S whose dimension is m-t. Thus s^{m-t} interactions are confounded. We shall show that only interactions between at least three factors are confounded. Otherwise we should have a b_t and b_t not both equal to 0 such that

$$(11.27) b_i y_i + b_i y_i = 0$$

for all points in S. But S contains $b_i = 0$ and similarly $b_i = 0$. Thus only interactions between more than 2 factors are confounded.

As an example we shall arrange the 27 treatment combinations of a three way experiment with every factor at three levels into 3 blocks of 9 each so that only interactions between 3 factors are confounded. We first have to find three independent linear functions of two variables, for instance

$$x, y, x + y.$$

Next we substitute the points of E.G.(2, 3) into these lines giving us the subset S of E.G.(3, 3) or the initial block of our design

$$\mathcal{S} = \{000,\,011,\,022,\,101,\,112,\,120,\,202,\,210,\,221\}$$

The other two blocks are obtained by adding, mod 3, the points 11 and 222 to S

$$8 + 111 = \{111, 122, 100, 212, 220, 201, 010, 021, 002\}$$

$$§ + 222 = \{222, 200, 211, 020, 001, 012, 121, 102, 110\}$$

To find the confounded interactions we choose two independent points in S, for instance, 011 and 101, and solve the equation

$$a \cdot 0 + b \cdot 1 + c \cdot 1 = 0$$
$$a \cdot 1 + b \cdot 0 + c \cdot 1 = 0$$

We obtain the solutions (a, b, c) = (112), (221). Thus only the two interaction components corresponding to (112) and the mean are confounded giving 3 orthogonal functions confounded.

Rao gives in his paper a more general method by which it is often possible to confound only interactions between more than d factors where d may be larger than 2.

If all treatment combinations are replicated in several sets of blocks each containing a framplete replication, it is also possible to confound some functions in some of the replications and to leave them unconfounded in others. This technique is known as partial confounding. The analysis of partially confounded designs is given by formulae analogous to 11.16, where however, \overline{L}_{α} is the mean value of L_{α} over those blocks where T_{α} is unconfounded and the sum

$$\sum_{i=1}^{r} (L_{\alpha i} - \overline{L}_{\alpha})^2$$

extends only over the same blocks.

F. Yates has in his previously mentioned publication given various designs where not all factors are at the same number of levels and some of the main effects and interactions between 2 factors are only partially, but never totally, confounded.

CHAPTER XII

Randomized Designs, Randomized Blocks, and Quasifactorial Designs

The use of orthogonal Latin squares and balanced incomplete block designs is only possible if the number of varieties, replications, and the block size fit into one of these designs. In cases where no suitable design of these two types can be found it is necessary to use other designs, some of which will be discussed in this book. This usually entails a loss in efficiency and sometimes also of mathematical precision.

A design which can be accommodated to any number of varieties, any block size, and any number to preplications can be obtained by arranging the varieties randomly over a field. The assumption of the underlying linear hypothesis is then given by

assumption of the density
$$E(y_{ij}) = v_i + \eta_j + \mu + \epsilon_{ii}$$
, $\sum_i v_i = \sum_i \eta_i = 0$,

where y_{ij} is the yield of the *i*th variety in the *j*th block, v_i is the effect of the *i*th variety, η_i the effect of the *j*th block, μ the general mean and the ϵ_{ij} are normally and independently distributed variables with mean 0 and the same but unknown variance. Since the varieties are assigned at random to the blocks, the block effect η_i becomes a random variable. However, η_i takes if the blocks are of equal size any of b values, $b_1 \cdots b_b$, with equal probability and therefore we cannot assume that $y'_{ij} = y_{ij} - v_i - \mu$ is normally distributed. Also $\sigma_{(\eta_i+\epsilon_ij)(\eta_i+\epsilon_ij)} = \sigma_{\eta_i\eta_i}$. If the blocks are of equal size each containing k varieties then

each containing
$$k$$
 varieties then
$$P(\eta_i = b_e , \eta_i = b_m) = \frac{k - \delta_{em}}{b(bk - 1)}, \qquad \delta_{em} = \begin{cases} 1 & \text{if } e = m \\ 0 & \text{if } e \neq m. \end{cases}$$

Hence

$$\sigma_{q_iq_j} = \sum_{\epsilon,m} \left(\frac{k-\delta_{\epsilon m}}{b(bk-1)} \right) b_\epsilon b_m = \frac{-\sum_i h_i^2}{b(bk-1)} \; .$$

Hence the y_{ii}^{\prime} are not independent. Thus it is not quite correct to treat such a design as a one way classification design, the classes being the varieties, as is usually done. The objections raised against this treatment are not serious if the sample is large, but may affect the size of the critical region for small samples. It must be admitted that one intuitively teels that a minor deviation from the assumptions will not greatly influence the distribution of F. A rigorous study of the deviation of F as computed from such randomized designs from the distribution computed in Chapter I has not been made. The theoretical statistician should not average of the fact that it is immaterial to the practical research worker whether the size of his critical region is exactly 5% or I or even 2% more or less. At any rate he cannot veto the use of slightly inaccurate methods as long as he has not succeeded in replacing them by accurate ones.

A rigorous treatment of the randomized design is possible if we consider not block but plot effects and regard these as chosen at random from a normal population of plot effects. Under these assumptions we may treat the design with complete rigor as a one way classification design. We are then ignoring the fact that neighboring plots have similar plot effects. Thus we are intentionally using a mathematical model which we know to be slightly different from the true situation. In this procedure we do, however, not differ from the physicist disregards air friction. One should also be aware of the fact, approximation to the truth.

An improvement over complete randomization is the arrangement of the varieties in randomized blocks. In this arrangement all varieties are replicated in each block and the design is then treated as a two way classification design by blocks and varieties. We then have to assume that the soil

fertility within the blocks is uniform. The position within the block is chosen at random for each variety.

In all designs which are based on randomization only, the block effects increase the error very considerably and in most cases a systematic arrangement, if available, is preferable.

In recent years the quasifactorial designs, particularly lattices and lattice squares, have become very popular. In these designs the techniques of partial confounding are utilized. As an example suppose that we have q_1q_2 varieties. These are arranged into a rectangle of q_1 rows and q_2 columns for instance for $q_1 = 3$, $q_2 = 4$.

Two sets of blocks are formed. The first set contains q_1 blocks of q_2 varieties each. The varieties in these blocks are those occurring in the 1st, 2nd, \cdots , q_1 st rows of the rectangle. The second set of blocks contains q_2 blocks with q_1 varieties each and the blocks contain the varieties in the 1st, 2nd, \cdots , q_2 nd column of the rectangle. Thus from 12.1 one obtains the following blocks:

$$(V_{11}, V_{12}, V_{13}, V_{14}), (V_{21}, V_{22}, V_{23}, V_{24}),$$

$$(V_{31}, V_{32}, V_{33}, V_{34}),$$

$$(V_{11}, V_{21}, V_{31}), (V_{12}, V_{22}, V_{32}),$$

$$(V_{13}, V_{23}, V_{33}), (V_{14}, V_{24}, V_{34}).$$

The whole design may be replicated any number of times. We may formally consider the varietal effects as if they were the result of the action of two factors at q_1 and q_2 levels respectively. Thus if V_{ij} is the effect of the variety v_{ij} we may write

(12.2)
$$V_{ij} = v_{ij} + v_{i} + v_{ij}, \sum_{i} v_{ij} = \sum_{i} v_{ij} = \sum_{i} v_{i} = \sum_{i} v_{i} = 0.$$

We may therefore regard the row set and the column set of blocks as two complete replications of a factorial design. The main effects of the first factor are confounded in the row set, the main effects of the second factor in the column set, the interaction remains unconfounded in both sets. Thus applying Theorem 11.3 with the modification appropriate to partially confounded arrangements discussed at the end of Chapter XI, we see that, because of 5.9, we have to minimize

we see that, because of 5.9, we have to minimize
$$Q = \sum_{l=1}^{2} \sum_{a_{1}} \sum_{a_{2}} [(l)A(1, 2; a_{1}, a_{2}) - r_{a_{1}a_{2}}]^{2} + q_{2} \sum_{a_{1}} [(2)A(1; a_{1}) - r_{a_{2}}]^{2}$$

$$\text{www.dbradti} \sum_{a_{2}} [(2)A(2; a_{1}) - r_{a_{2}}]^{2},$$

where the quantities $(l)A(1, 2; a_1, a_2), (l)A(1; a_1), (l)A(2; a_2)$ are computed by formula 5.5 from the lth set of blocks. Thus the least square estimates $\hat{v}_{a_1a_2}$, \hat{v}_{a_1} , \hat{v}_{a_2} , become

(12.4)
$$\hat{v}_{a_1a_2} = \frac{1}{2} \sum_{l=1}^{2} (l) A(1, 2; a_1, a_2),$$

$$\hat{v}_{a_1} = (2) A(1; a_1), \hat{v}_{a_2} = (1) A(2; a_2).$$
 Hence

Hence

(12.5)
$$Q_a = \sum_{l=1}^{2} \sum_{a_1} \sum_{a_2} [(l)A(1, 2; a_1, a_2) - \frac{1}{2}(1)A(1, 2; a_1, a_2) + (2)A(1, 2; a_1, a_2)]^2$$

and if we test the hypothesis $V_{a_1a_2} = 0$, $a_1 = 1$, \cdots , g_1 , $a_2 = 1, \ldots, q_2$

(12.6)
$$Q_r - Q_a = \sum_{\alpha_1} \sum_{\alpha_2} \hat{v}_{\alpha_1\alpha_2}^2 + q_2 \sum_{\alpha_1} \hat{v}_{\alpha_1}^2 + q_1 \sum_{\alpha_2} \hat{v}_{\cdot\alpha_1}^2$$
.

The idea of a lattice may be generalized. Suppose we wish to test $q_1 \cdots q_r$ varieties. We may then consider the varietal effects as treatment combinations in a factorial experiment. Thus we denote the varietal effects by $V_{a_1...a_r}$ $1 \le a_i \le q_i$ and write

$$V_{a_1, \dots, a_r} = \sum_{\alpha=1}^{r} \sum_{j \dots r} v(i_1, \dots, i_{\alpha}; a_i, \dots, a_{i_{\alpha}}),$$

$$\sum_{\alpha i} v(i_1, \dots, i_k; a_1, \dots, a_k) = 0.$$

We then form r sets of blocks. The blocks of the first set are formed by keeping the indices a_2, \dots, a_r , fixed and allowing a_i to vary from 1 to q_1 . Thus $q_2 \cdots q_r$ blocks are obtained. The blocks in the *i*th set are formed similarly by keeping $a_1, \dots, a_{i-1}, a_{i+1}, \dots, a_r$ fixed and allowing a_i to vary from 1 to q_i . In the *i*th set all interentials which do not contain the *i*th factor are confounded giving $q_1 \cdots q_{i-1}q_{i+1} \cdots q_r$ interaction components confounded. The remaining interaction components are by Theorem 11.2 orthogonal to the blocks. Thus to obtain Q_a we have to minimize the sum of the unconfounded parts of the right side of 5.9 over all the r sets of blocks. That is to say we have to minimize

$$Q = \sum_{\alpha=1}^{n} \sum_{1, \dots, r} \frac{q_{1} \cdots q_{r}}{q_{i_{\alpha}} \cdots q_{i_{\alpha}}} \sum_{a_{i_{1}}} \cdots \sum_{a_{i_{\alpha}}} \sum_{i=1}^{\alpha} \cdots \sum_{a_{i_{\alpha}}} \sum_{i=1}^{n} \cdots \sum_{a_{i_{\alpha}}} \sum_{a_{i_{\alpha}}} \cdots \sum_{a_{i_{\alpha}}$$

where $(l)\Lambda(i_1, \dots, i_{\alpha}; a_i, \dots, a_{i_{\alpha}})$ is obtained by 5.5 from the lth set of blocks. Thus

(12.9)
$$\hat{v}(i_1, \dots, i_{\alpha}; a_{i_1}, \dots, a_{i_{\alpha}}) = \frac{1}{\alpha} \sum_{i=1}^{\alpha} (i_i) A(i_1, \dots, i_{\alpha}; a_{i_1}, \dots, a_{i_{\alpha}}).$$

Hence

$$Q_{a} = \sum_{\alpha=1}^{r} \sum_{1,\dots,r} \frac{q_{1} \dots q_{r}}{q_{i_{1}} \dots q_{i_{\alpha}}} \sum_{a_{i_{1}} \dots \sum_{a_{i_{r}}} \dots \sum_{a_{1}} \dots$$

 $=\alpha\{\hat{v}(i_1,\dots,i_n); a_{i_1},\dots,a_{i_n}\}^2\}.$ If the hypothesis $V_{a_1\cdots a_r}=0,\ 1\leq a_1\leq a_1\leq a_1$ is tested we obtain $Q_r-Q_a=\sum_{v=1}^r\sum_{\substack{q_1,\dots,q_1\\\text{www.dbraullibrary.org.in}}\frac{q_1}{q_1}\sum_{\substack{q_1,\dots,q_1\\q_1,\dots,q_{1_n}}}\dots\sum_{\substack{q_{1_n}\\q_{1_n}}}\sum_{a_{i_1}}\alpha$ obtain

$$Q_r - Q_a = \sum_{\text{www.dbraullibrary.org}} \sum_{\substack{q_1 + \cdots + q_r = \sum \\ q_{1n} = q_{1n} = 2}} \sum_{\substack{q_1 + \cdots + q_{1n} = 2 \\ q_{1n} = 2}} \sum_{\substack{q_1 + \cdots + q_{1n} = 2 \\ q_{1n} = 2}} \alpha$$

$$[\hat{v}(i_1, \cdots, i_n; a_{i_1}, \cdots, a_{i_n})]^2.$$

The degrees of freedom for Q_a are

$$\sum_{\alpha=1}^{r} \sum_{i_1,\dots,i_r} (\alpha-1)(q_{i_1}-1) \cdots (q_{i_n}-1)$$

because each of the $(q_{i_1}-1)\cdots(q_{i_n}-1)$ independent components of the interaction between the factors i_1 , \cdots , i_a contributes $(\alpha - 1)$ squares of independent linear functions to

 Q_a . The degrees of freedom for $Q_r = Q_a$ are $(q_1 \cdots q_r) = 1$. We proceed to compute the variances of the varietal effects and of differences between them. In doing this we may, without loss of generality, assume that $V_{a_i...a_r} = 0, \ 1 \le a_i \le q_i$. Applying Cochran's Theorem 2.1 to 5.7 we see that

$$\sum_{a_{i_1}} \cdots \sum_{a_{i_\alpha}} \frac{q_1 \cdots q_r}{q_{i_1} \cdots q_{i_\alpha}} (A(i_1, \dots, i_\alpha; a_{i_1}, \dots, a_{i_\alpha}))^2$$
the a_i^2 the a_i^2

has the χ^2 distribution with $(q_{i_*}-1)\cdots(q_{i_*}-1)$ degrees of freedom. The quantities $A(i_1, \dots, i_a; a_{i_1}, \dots, a_{i_a})$ $1 \le i_1 \le i_2 \le i_3 \le i_4 \le i_4 \le i_5 \le i$ $a_{i_i} \leq q_{i_i}$ are composed from independent observations in

exactly the same fashion and hence must have the same variance $\sigma^2_{A(i_1,\dots,i_n)}$. Hence

$$\frac{q_1 \cdots q_r}{q_{i_1} \cdots q_{i_n}} q_{i_1} \cdots q_{i_n} \sigma^2_{A(i_1, \dots, i_n)}$$

$$= (q_{i_1} - 1) \cdots (q_{i_n} - 1) \sigma^2$$

Thus

$$(12.12) \sigma_{A(i_1,\dots,i_n)}^2 = \frac{(q_{i_1} - 1) \cdots (q_{i_n} - 1)}{q_1 \cdots q_r} \sigma^2.$$

Let $\hat{V}_{a,...a_r}$ be the least square estimate of $V_{a,...a_r}$ then

$$(12.13) \quad \hat{V}_{a_1, \dots, a_r} = \sum_{\alpha=1}^{r} \sum_{i_1, \dots, r} \hat{v}(i_1, \dots, i_{\alpha}; a_{i_1}, \dots, a_{i_{\alpha}}).$$

But by 12.9 the $\hat{v}(i_1, \dots, i_{\alpha}; a_{i_1}, \dots, a_{i_{\alpha}})$ are sums of components of the interaction detacking detacking for i_1, \dots, i_{α} and hence by Theorem 11.1 orthogonal to each other, moreover by 12.9 and 12.12 $\hat{v}(i_1, \dots, i_{\alpha}; a_{i_1}, \dots, a_{i_{\alpha}})$ has the variance

$$\frac{1}{\alpha} \frac{(q_{i_1}-1)\cdots(q_{i_\sigma}-1)}{q_1\cdots q_r} \sigma^2.$$

Thus

(12.14)
$$\sigma_{\hat{\varphi}_{\alpha_{i_1}, \dots, \alpha_{r}}}^{\hat{\sigma}_{\hat{\varphi}_{\alpha_{i_1}, \dots, \alpha_{r}}}} = \sigma^2 \sum_{\alpha=1}^{r} \frac{1}{\alpha} \sum_{1, \dots, r} \frac{(q_{i_1}-1) \cdots (q_{i_{\alpha}}-1)}{q_1 \cdots q_r} .$$

To obtain the variance of the difference between two factors we first compute the covariance between $A(i_1, \dots, i_{\alpha}; a_{i_1}, \dots, a_{i_{\alpha}})$ and $A(i_1, \dots, i_s, i_{s+1}, \dots, i_{\alpha}; a_{i_1}, \dots, a_{i_s}, b_{i_{s+1}}, \dots, b_{i_{\alpha}})$ where $a_{i_k} \neq b_{i_k}$. We first compute the coefficient of $x_{c_1 \dots c_s}$ in $A(i_1, \dots, i_{\alpha}; a_{i_1}, \dots, a_{i_{\alpha}})$. Suppose that $c_{i_1} = a_{i_1}, \dots, c_{i_i} = a_{i_1}, c_{i_{i+1}} \neq a_{i_{i+1}}, \dots, c_{i_{\alpha}} \neq a_{i_{\alpha}}$. Then $x_{c_1 \dots c_s}$ occurs in 5.5 only in terms for which $k_1 \dots k_{\beta}$ are chosen from i_1, \dots, i_j . The coefficient of $x_{c_1 \dots c_s}$ in $x(k_1, \dots, k_{\beta}; c_{k_1}, \dots, c_{k_{\beta}})$ is $(q_{k_1}, \dots, q_{k_{\beta}})/(q_1, \dots, q_r)$. Hence the coefficient of $x_{c_1 \dots c_s}$ in $A(i_1, \dots, i_{\alpha}; a_{i_1}, \dots, a_{i_{\alpha}})$ becomes

(12.15)
$$\sum_{\beta=0}^{i} (-1)^{\alpha-\beta} \sum_{\substack{x_1, \dots, x_j = q_1 + \dots + q_j \\ q_1, \dots, q_j = q_j = \dots + q_j}} q_{x_1, \dots, q_j}$$

$$= \frac{(-1)^{\alpha-j}}{q_1, \dots, q_r} \sum_{\beta=0}^{j} \sum_{\substack{x_1, \dots, x_j = q_j \\ q_1, \dots, q_r = q_r}} (-1)^{\beta-\beta} q_{x_1}, \dots, q_{t_{\beta}}$$

$$= \frac{(-1)^{\alpha-j}}{q_1, \dots, q_r} (q_{x_1} - 1) \dots (q_{x_r} - 1).$$
From 5.4 and 1.

From 5.4 we then have

From 5.4 we then have
$$(12.16) x_{c_1, \dots, c_r} = \sum_{\beta=0}^{r} \sum_{1, \dots, r} A(k_1, \dots, k_{\beta}; c_{k_1}, \dots, c_{k_{\beta}}).$$
We make the same and the same

We multiply 12.16 by $A(i_1, \dots, i_{\alpha}; a_{i_1}, \dots, a_{i_{\alpha}})$ and take expectations on both sides. The left side then becomes

www.vall)
$$\hat{q}_1$$
 \dots q_r $(q_{i_t}-1)$ \dots $(q_{i_t}-1)\sigma^2$

On the right side we obtain the covariance $\sigma[A(i_1, \dots, i_n)]$ a_{i_1}, \dots, a_{i_n} $A(i_1, \dots, i_n, c_{i_1}, \dots, c_{i_n})$ of $A(i_1, \dots, i_n)$ a_{i_1}, \dots, a_{i_d} and $A(i_1, \dots, i_{\alpha}; c_i, \dots, c_{i_{\alpha}})$ since interactions between different factors are by Theorem 11.1 orthogonal and therefore independent. Thus

$$\sigma[A(i_1, \ldots, i_i i_{i_{i+1}}, \cdots, i_{\alpha}; a_{i_1}, \cdots, a_{i_s} a_{i_{s+1}}, \cdots, a_{i_s})]$$

$$(12.17) \qquad (-1)^{\alpha-s}$$

$$= \frac{(-1)^{\alpha-s}}{q_1 \cdots q_r} (q_{i_1} - 1) \cdots (q_{i_s} - 1)\sigma^2 \quad \text{for } b_{i_k} \neq a_{i_k}.$$

We therefore have

$$\sigma^{2}[A(i_{1}, \dots, i_{\alpha}; a_{i_{1}}, \dots, a_{i_{\alpha}}) - A(i_{1}, \dots, i_{r}, i_{s+1}, \dots, i_{s+1}, \dots, i_{\alpha}; a_{i_{1}}, \dots, a_{i_{s}}, b_{i_{s+1}}, \dots, b_{i_{\alpha}})] = \frac{2}{q_{1} \dots q_{r}} [(q_{i_{1}} - 1) \dots (q_{i_{\alpha}} - 1) + (-1)^{\alpha^{-\alpha+1}} \dots (q_{i_{1}} - 1) \dots (q_{i_{r}} - 1)] \sigma^{2}$$

Thus

$$\sigma^{2}(V_{a_{1},...,a_{r}} - V_{a_{1},...,a_{s},b_{s+1},...,b_{r}})$$

$$= \frac{2\sigma^{2}}{q_{1}} \sum_{\alpha=0}^{s} \sum_{1,...,s} (q_{i_{1}} - 1) \cdots (q_{i_{\alpha}} - 1)$$

$$(12.19)$$

$$\sum_{\beta=0}^{r-s} \sum_{s+1,...,r} \frac{1}{\alpha + \beta} [(q_{k_{1}} - 1) \cdots (q_{k_{\beta}} - 1) + (-1)^{\beta+1}].$$

$$(12.19)$$

In the case of a two dimensional lattice 12.19 reduces to

the case of a two dimensional lattice 12.19 leaders
$$\sigma_{V_{i,j}-V_{k,l}}^2 = \begin{cases} \sigma^2 & q_1q_2+q_1+q_2\\ q_1q_2 & i
otin k, j
eq l, \\ \sigma^2 & q_1q_2 & q_2 & q_2 \\ q_1q_2 & q_2 & q_2 & q_2 \end{cases}$$
, a three dimensional lattice

In a three dimensional lattic

The calculation of the efficiency factors with respect to the varietal estimates and differences between them is left to the reader.

If the number of varieties is the square of a power of a

prime, then the experiment may be $\{a_i^{(i)}\}_{i=1}^{n}$ to advantage in a so called lattice square, which like a 1 consequare permits us to break the soil fertility into two remandular components. In a lattice square m^2 varieties are replicated in r square arrays each with m^2 plots in such a way that every pair of varieties occurs together in the same row or the same column the same number λ of times. To construct a lattice equare one needs (m-1) orthogonal squares. The individual boxes of these squares may be denoted by r_1, \ldots, r_m . For there with the row and column number of the Latin square each box corresponds to (m+1) numbers $i_1, \ldots, i_m = 1$ for which $i_m = 1$ have the property that for every $0 \leq p$, $r \leq m + 1$ and each $r_m = r_m = 1$.

We now form the interesting the varieties into a square according to the first pair of coordinates. That is to say if $v_{\alpha}=(i_1^{(\alpha)},i_2^{(\alpha)},\cdots)$ then v_{α} is placed into the i_i st row and the i2nd column. The second square is similarly arranged according to i_3 , i_4 and so forth. If m is odd we obtain in this manner (m+1)/2 replications. Since the rows and the columns of the squares are the lines of a finite Euclidean plane whose points are the varieties, it follows that every pair of varieties occurs just once together either in a row or in a column. If m is even we arrange according to the indices (i_1, i_2) , (i_3, i_4) , the country (i_{m+1}, i_m) , (i_{m+1}, i_1) , ..., (i_m, i_{m+1}) . Thus every line of the corresponding Euclidean Geometry occurs twice, once as a row and once as a column, and therefore every pair of varieties will appear together twice, once in the same row and once in the same column. We shall exemplify the procedure by constructing a lattice square for 9 and for 4 varieties. We start from 2 orthogonal 3 sided Latin squares

1,1	$2_{\mathfrak{v}_{\mathfrak{p}}}2$	3,,3
2.3	3. 1	1,,2
3,,2	1,,3	2, 1

The two squares of the lattice square then are

Similarly from

We obtain 3 squares of a lattice square with 4 varieties

The assumptions underlying the lattice square are

The assumptions underlying the
$$u_i^{(\alpha)} = r_i^{(\alpha)} + c_i^{(\alpha)} + v_{k\alpha_{ij}} + \mu^{(\alpha)} + \mu + \epsilon_{ij}^{(\alpha)},$$

$$\sum_i r_i^{(\alpha)} = \sum_i c_i^{(\alpha)} = \sum_{\alpha} \mu^{(\alpha)} = \sum_k v_k = 0,$$

where

is the observed yield in the ith row and jth column of the αth replication.

is the effect of the *i*th row in the α th replication.

 $c_i^{(\alpha)}$ is the effect of the jth column in the α th replication.

 $p_{e_{i,j}}$ is the effect of the variety in the *i*th row and *j*th column of the α th replication.

is the effect of the α th replication.

is the general mean.

The $\epsilon_{ij}^{(\alpha)}$ are normally and independently distributed random variables with mean 0 and the same but unknown variance σ^2 .

The equations resulting from minimizing

The equations resulting from minimates
$$Q = \sum_{\alpha} \sum_{i} \sum_{j} (y_{ij}^{(\alpha)} - r_{i}^{(\alpha)} - c_{j}^{(\alpha)} - v_{k^{\alpha}i}, -\mu^{\alpha} - \mu)^{2}$$

become, if the Lagrange operator is ignored,

$$\hat{\mu} = \frac{1}{rm^2} \sum_{\alpha} \sum_{i} \sum_{j} y_{ij}^{(\alpha)} = y,$$

$$\hat{\mu}^{(\alpha)} = \frac{1}{m^2} \sum_{i} \sum_{j} y_{ij}^{(\alpha)} - y = y^{(\alpha)} - y,$$

$$(12.21) \sum_{ik} y_{ij}^{(\alpha)} = \sum_{ik} \hat{r}_{i}^{(\alpha)} + \sum_{ik} c_{i}^{(\alpha)} + r\hat{r}_{i} + r\hat{r}_{ij} + r\hat{\mu}_{ij},$$

$$my_{i}^{(\alpha)} = m\hat{r}_{i}^{(\alpha)} + \sum_{i,j} \hat{v}_{i} + m\hat{\mu}^{(\alpha)} + m\hat{\mu}_{ij},$$

$$my_{ij}^{(\alpha)} = m\hat{c}_{i}^{(\alpha)} + \sum_{i,j} \hat{v}_{i} + m\hat{\mu}^{(\alpha)} + m\hat{\mu}_{ij},$$
where $\sum_{i} docation = kilonic is a simple for a simple fo$

where $\sum_{i,k}$ denotes summation ever all plots containing the kth variety, $\sum_{i,j} (\alpha) (\sum_{i,j} (\alpha))$ denotes summation over all plots contained in the ith row, (or column), of the α th replication.

Summing the fourth and fifth equations over all rows and columns respectively which contain the kth variety we obtain

(12.22)
$$m\left[\sum_{\tau_{k}} (y_{i}^{(\alpha)} - y) + \sum_{v_{k}} (y_{i}^{(\alpha)} - y)\right] \\ = m \sum_{\tau_{k}} \hat{r}_{i}^{(\alpha)} + m \sum_{v_{k}} \hat{c}_{i}^{(\alpha)} + (2r - \lambda)v_{k}.$$

Dividing 12.22 by m and subtracting from 12.21 yields on account of r=(m+1)/2 λ

(12.23)
$$\hat{\theta}_k = \frac{2}{\lambda(m-1)} \sum_{i,k} (y_{ij}^{(\alpha)} - y_i^{(\alpha)} - y_{ij}^{(\alpha)} + y).$$

Hence

(12.24)
$$\begin{cases} \hat{r}_{i}^{(\alpha)} = y_{i}^{(\alpha)} - y^{(\alpha)} - \frac{1}{m} \sum_{r_{i} \in \alpha_{i}} \hat{v}_{i}, \\ \hat{c}_{i}^{(\alpha)} = y_{i}^{(\alpha)} - y^{(\alpha)} - \frac{1}{m} \sum_{\sigma_{i} \in \alpha_{i}} \hat{v}_{i}. \end{cases}$$

If $\hat{r}_{i}^{*(\alpha)}$, $\hat{c}_{i}^{*(\alpha)}$ are the least square estimates of $r_{i}^{(\alpha)}$, $c_{i}^{(\alpha)}$ under the hypothesis $v_i = 0, j = (1, \dots, m^2)$ then

$$\hat{r}_{i}^{*(\alpha)} = y_{i}^{(\alpha)} - y_{i}^{(\alpha)},$$

$$\hat{c}_{j}^{*(\alpha)} = y_{i}^{(\alpha)} - y_{i}^{(\alpha)}.$$
(12.25)

It is easily verified that these solutions satisfy the restrictions igwedgein 12.20. Hence by Theorem 4.2

It is easily verified that these solutions satisfy the restrictions in 12.20. Hence by Theorem 4.2

$$Q_{a} = \sum_{\alpha} \sum_{i} \sum_{j} (y_{ii}^{(\alpha)})^{2} \\ - m \sum_{\alpha} \left[\sum_{i} (y_{ii}^{(\alpha)})^{2} + \sum_{j} (y_{ii}^{(\alpha)})^{2} \right] \\ - \sum_{\alpha} \sum_{i} \sum_{j} \left[\hat{v}_{k^{\alpha}, i} - \frac{1}{m} \sum_{(\alpha)} \hat{v}_{i} - \frac{1}{m} \sum_{(\alpha)} \hat{v}_{i} \right]^{2} \\ + m^{2} \sum_{\alpha} (y^{(\alpha)})^{2},$$

$$(12.26)$$

$$Q_{r} - Q_{\alpha} = \sum_{\alpha} \sum_{i} \sum_{j} \left(\hat{v}_{k^{\alpha}, i} - \frac{1}{m} \sum_{(\alpha)} \hat{v}_{i} - \frac{1}{m} \sum_{(\alpha)} \hat{v}_{i} \right) \\ - \frac{1}{m} \sum_{(\alpha)} \hat{v}_{i} \right)^{2}.$$

We shall now compute the variance of \hat{v}_k . We shall simply compute the coefficients of the observations entering into \hat{v}_b . There are r observations on the kth variety which enter into θ_{\star} with the coefficient $[2(m-1)]/(\lambda m^2)$. Further 2r(m-1)varieties different from v_* each of which occurs either in a row or in a column together with v_k which enter into ϑ_k with the coefficient $-2/(\lambda m^2)$ and $r(m-1)^2$ observations not together with the kth variety in a row or column and therefore entering with the coefficient $2/[\lambda m^2(m-1)]$. Thus

$$\begin{split} \frac{\sigma_{\frac{\sigma_{k}}{\sigma^{2}}}^{2}}{\sigma^{2}} &= \frac{4r(m-1)^{2}}{\lambda^{2}m^{4}} + \frac{2r(m-1)\cdot 4}{\lambda^{2}m^{4}} + \frac{4r}{\lambda^{2}m^{4}} \\ &= \frac{4rm^{2}}{\lambda^{2}m^{4}} = \frac{4r}{\lambda^{2}m^{2}} = \frac{2(m+1)}{\lambda m^{2}} \,. \end{split}$$

Since every pair of varieties occurs exactly λ times $Q_r = Q_a$ must be symmetric in the θ_k . Therefore applying Theorem 4.5, 12.26 simplifies to

$$Q_{a} = \sum_{\alpha} \sum_{i} \sum_{j} (y_{ij}^{(\alpha)})^{2} - m \sum_{\alpha} \left[\sum_{i} (y_{i}^{(\alpha)})^{2} + \sum_{i} (y_{i}^{(\alpha)})^{2} \right] - (r - \lambda) \sum_{k} \hat{v}_{k}^{2} + m^{2} \sum_{\alpha} (y_{i}^{(\alpha)})^{2}$$

$$Q_{r} - Q_{\alpha} = (r - \lambda) \sum_{k} \hat{v}_{k}^{2}.$$

The degrees of freedom of Q_a are $m^2r = (m^2 - 1) - 2r(m-1) - (r-1) - 1$ and of $Q_r - Q_a$, $m^2 - 1$.

The variance of $\hat{v}_i - \hat{v}_i$ can also be obtained by simple enumeration of the authorizations entering into $\hat{v}_i - \hat{v}_i$ and turns out to be

$$\frac{\sigma_{(\theta_i-\theta_j)}^2}{\sigma^2} = \frac{2}{r-\lambda} \ .$$

The details of this enumeration are left to the reader.

The efficiency factors with respect to \hat{v} , and with respect to \hat{v} , $-\hat{v}$, both turn out to be (m-1)/(m+1).

Several more complicated designs are in use which all evaluate the idea of treating the varietal effects as treatment combinations of several factors. It is for instance always possible to superimpose a Latin square on a square lattice and then to introduce a third set of blocks by grouping the varieties according to the letters of a Latin square. Such arrangements are called triple lattices. Similarly with a set of r orthogonal squares it is possible to obtain an (r+2) fold lattice. If r=(p-1) where p is the length of the side then the resulting design is termed a balanced lattice. The designs discussed in this chapter were invented by F. Yates and proposed by him in several important publications. (Journal of Agr. Science 26, pp. 424-455, Ann. Eugenics, pp. 319-332, Journal of Agricultural Science 30, pp. 672-728.)

CHAPTER XIII

Analysis of Covariance

We shall consider in this chapter the following linear hypothesis. Suppose we have N observations y_1 , y_2 , \cdots , y_N and constants $x_{1\alpha}$, \cdots , $x_{p\alpha}(\alpha = 1, \cdots, N)$. We assume

$$E(y_{\alpha}) = \mu_{\alpha} + \beta_{1}x_{1\alpha} + \cdots + \beta_{p}x_{p\alpha} \quad \alpha = 1, \cdots, N,$$

$$\sum_{\alpha} \lambda_{i\gamma}\mu_{\gamma} = 0 \quad i = 1, \cdots, s \leq N \quad \text{rank} \ (\lambda_{i\gamma}) = s > p.$$

The hypotheses to be tested may concern either the μ_a or the β_i . Accordingly we shall consider two kinds of hypotheses

(13.2)
$$H_1: \sum_{\tau} \lambda_{i\tau} \mu_{\tau} = 0, \quad i = s + 1, \dots, r \leq N,$$

$$\operatorname{rank}(\lambda_{i\tau}) = r,$$

$$H_2: \sum_{i} \nu_{ii} \beta_i = 0, \quad i = 1, \dots, p.$$

Both hypotheses are linear hypotheses and Theorem 4.1 applies. The degrees of freedom for Q_a are obtained as follows: The expectations $E(y_a)$, $\alpha=1,\cdots,N$, are first expressed by the N+p parameters μ_a , $\alpha=1,\cdots,N$; β_i , $i=1,\cdots,p$. The linear restrictions in 13.1 enable us to eliminate s of the μ_a . If we arrange it so that μ_1 , \cdots , μ_s are eliminated this will lead to

(13.3)
$$E(y_{\alpha}) = \sum_{i=s+1}^{N} a_{i\alpha}\mu_{i} + \beta_{1}x_{1\alpha} + \cdots + \beta_{p}x_{p\alpha}.$$

If the matrix

$$\begin{pmatrix}
a_{(s+1)1} & \cdots & a_{N1} & x_{11} & \cdots & x_{p1} \\
\vdots & & \ddots & & \vdots \\
\vdots & & \ddots & & \vdots \\
\vdots & & \ddots & & \ddots \\
\vdots & & \ddots &$$

has the rank N+p-s then we have expressed the N expectations $E(y_a)$ by N+p-s parameters and this is equivalent to s-p linear restrictions on $E(y_a)$. Thus Q_s will have s-p degrees of freedom if the matrix 13.4 has the rank N+p-s. The degrees of freedom for Q_s-Q_s are obtained by a straight forward application of Theorem 4.1.

The analysis of covariance is frequently applied to r way classification designs. Thus we might have taken observations on the weight gains of animals from r different races at k different diets and might have recorded the initial weight of each animal. Assuming that the interaction is 0 and that weight gains of animals depend linearly on the initial weight we can write our assumptions as

$$E(y_{ij}) = \mu_i$$
 ψ_w we abtraulibrany, or g . In $i = 1, \cdots, r; j = 1, \cdots, k$,

where y_{ij} is the weight gain of the animal from the *i*th race receiving the *j*th diet and x_{ij} is the initial weight of this animal. The hypotheses to be tested may be

$$H_1: \mu_i = 0, i = 1, \dots, r_i; H_2: \mu_{i,j} = 0, j = 1, \dots, k;$$

$$H_3: \beta = 0.$$

The tests for these hypotheses are obtained by a straight forward application of Theorem 4.1.

XIV CHAPTER

Interblock Estimates and Interblock Variance

THE BLOCK WITICH WILL CONTAIN a certain set of treatment combinations or varieties is actually always chosen at random so that the block effect may also be regarded as a random variable. This point of view makes it possible to obtain unbiased and consistent estimates also of confounded interactions in a factorial experiment. Thus from formula 11.13 we see that if L_{α} presents the linear form $\sum_{\beta} t_{\alpha\beta} x_{\beta}$ corresponding to the linear form $S_{\alpha} = \sum_{\beta} t_{\alpha\beta} T_{\beta}$ in the treatment combinations T_{θ} then

$$L_{\alpha} = S_{\alpha} + \sum_{\beta}^{\text{www.dbraulibrary.org.in}} t_{\alpha\beta} t_{\beta} + \sum_{\beta}^{\text{tages.}} t_{\alpha\beta} t_{\beta}.$$

where the ϵ_{β} are normally and independently distributed with mean 0 and variance σ^2 . If the block effects are considered as normally distributed random variables independent of each other and of the random error ϵ_a with variance ${\sigma'}^2$ and mean γ , then L_{α} is an unbiased estimate of S_{α} if S_{α} is not the mean and thus comparisons between confounded linear functions are still possible. The variance of a confounded form L_a becomes by 11.14 $u^2 \sigma'^2 \sum_i c_{\alpha i}^2 + \sigma^2 \sum_{\beta} t_{\alpha \beta}^2$. Now $u \sum_i c_{\alpha i}^2 = 1$, $\sum_{\beta} t_{\alpha \beta}^2 = 1$ because of the orthogonality of the substitution. Hence

(14.2)
$$\sigma_{Lu}^2 = u\sigma'^2 + \sigma^2.$$

If L_{β} is another confounded linear form then $\sigma_{L_{\alpha}L_{\beta}}$ $u^2 \sigma'^2 \sum_{i}^{p} c_{\alpha i} c_{\beta i} + \sigma^2 \sum_{\gamma} t_{\alpha \gamma} t_{\beta \gamma} = 0$ because of the orthogonality of the matrix $(t_{\alpha\beta})$ and the assumption of independence of the block effects. Similarly $\sigma_{L_{\alpha}L_{\beta}} = 0$ if L_{α} is confounded and L_{β} unconfounded. Thus comparisons involving confounded linear functions become possible. The estimates of L_{α} obtained in this way are called interblock estimates and the comparisons between interblock estimates are termed interblock comparisons. The variance $u\sigma'^2 + \sigma^2$ can be estimated if several complete replications are available. The confounded forms are then treated as a separate set of observations all with the same variance and with means S_{σ} . As long as no partial confounding takes place confounded linear forms may be compared with each other applying the F test, with Q_{σ} being obtained from the sum of the squares of deviations of these forms from their mean values. The degrees of freedom of Q_{σ} are (r-1)f where r is the number of replications and f the number of linear forms confounded. For comparisons of confounded with unconfounded forms no exact test is available at present.

If the linear form S_a in the treatment combinations is confounded in some replications and orthogonal to the blocks in other replications, we shall obtain two independent estimates of S_a : intrablockbrestimates of from those replications where S_a is orthogonal to the blocks and interblock estimates from replications in which S_a is confounded with all the blocks. If we would know the interblock and the intrablock variance then these two estimates could be combined so as to yield minimum variance. Let L_a and L'_a be the intrablock and the interblock estimate respectively of S_a and let σ_a^2 and $\sigma_a'^2$ be the variances of L_a and L'_a respectively. L_a and L'_a are independent being derived from different observations and both are also independent of Q_a as may be seen from Theorem 11.3. An easy calculation shows that

$$L_{\alpha}^* = \frac{\sigma_{\alpha}^{\prime 2} L_{\alpha} + \sigma_{\alpha}^2 L_{\alpha}^{\prime}}{\sigma_{\alpha}^{\prime 2} + \sigma_{\alpha}^2}$$

has the smallest variance among all linear combinations of the form $(aL_{\alpha} + bL'_{\alpha})/(a + b)$. Moreover L_{α}^{*} is normally distributed with variance $(\sigma'_{\alpha}^{2}\sigma'_{\alpha})/(\sigma'_{\alpha}^{2} + \sigma'_{\alpha})$ so that

(14.3)
$$F = \frac{f}{1} \frac{{\sigma'}_{\alpha}^2 + {\sigma'}_{\alpha}^2}{{\sigma'}_{\alpha}^2 {\sigma_{\alpha}^2}} \frac{L_{\alpha}^{*2}}{Q_{\alpha}/\sigma^2}.$$

has the F distribution with 1 and f degrees of freedom where f is the number of degrees of freedom for Q_a as given by Theorem 11.3 and σ_a^2 is some known multiple of σ^2 . However σ^2 and

 σ'^2 are not accurately known. As an estimate of σ^2 we may use Q_a/f and an estimate of $u{\sigma'}^2 + \sigma^2$ may be obtained from those linear forms which are confounded in more than one replication and also by comparing the observations on the same linear form in replications where it is confounded with those in replications where it is unconfounded. However, if we replace σ^2 and ${\sigma'}^2$ by these estimates then F as given by 14.3 does not have the F distribution. If the estimates σ^2 and ${\sigma'}^2$ are both based on a large number of degrees of freedom then F in 14.3 will at least be approximately distributed as F since σ^2 and ${\sigma'}^2$ converge stochastically to their true values. Thus although we might gain somewhat in efficiency by utilizing the interblock estimates we do so at the expense of mathematical rigor. It may also be remembered that a decrease in variance is not necessarily equivalent to arginorease in power. Formula 14.2 shows moreover that the variance of the inter-block estimates is large compared to the variance of the intrablock estimates, whenever there is any appreciable variation from block to block. Thus a sizeable advantage is derived from the use of the interblock estimates only if the blocks are nearly uniform in fertility.

In quasifactorial designs the procedure described in the preceding paragraph applies without change. In other designs for varietal trials, for instance incomplete balanced blocks, the application is not immediate. We note however that the sums of the yields of whole blocks involve differences in the varietal content of the blocks. Thus estimates of the varietal effects may be obtained by considering the regression of the block totals on the varietal effects. The estimates of the varietal effects obtained in this manner will be linear functions of the block totals. We shall show that the block totals are independent of the intrablock estimates and independent of Q_a . We refer to the assumptions 7.8 of a general arrangement of varieties in blocks where however no variety occurs more than once in any block. The estimate \hat{v}_i is consistent by 4.49. Hence if $\hat{v}_i = \sum_i \lambda_{\alpha} x_{\alpha}$ where x_1, \cdots, x_N are the observations then $E(\hat{v}_i) = v_i + \sum_i \lambda_{\alpha} b_{i\alpha} + \mu \sum_i \lambda_{\alpha}$, where x_{α} lies in the ith

block. Since θ_i is an unbiased estimate of v, we must have $\sum_{x_{\alpha} \in b_i} \lambda_{\alpha} = \sum_{x_{\alpha} \in b_i} \lambda_{\alpha}$ for all i and j and $\sum_{\alpha} \lambda_{\alpha} = 0$. Hence $\sum_{x_{\alpha} \in b_i} \lambda_{\alpha} = 0$ which means that θ_i is orthogonal to, and therefore independent of the block sums.

If in the set up 7.8 we test the hypothesis $v_*=0$ then the estimates of the block effects will be given by the block averages. Applying Theorem 4.2 and 4.1 we then see that the block sums are also independent of Q_a obtained by minimizing 7.9. Since the interblock estimates are linear functions of the block sums it follows that they are independent of the intrablock estimates and of Q_a computed from the intrablock estimates. Interblock and intrablock estimates may be combined as in factorial experiments so as to give minimum variance. For this process it is necessary to estimate the interblock variance. To obtain such an estimate of the interblock variance obtain such an estimate of the interblock variance. To obtain such an estimate of the interblock variance of the assumptions 7.8 in the form

assumptions 7.8 in the form
$$E(y_{ij}) = v_i + b_i \qquad \sum_i v_i = 0.$$

We shall also assume that no variety occurs twice in the same block.

If we test the hypothesis $b_i = \mu$; $j = 1, \dots, b$ then the regression value of y_{ii} becomes V_i/r_i and hence by Theorem 4.2

$$(14.5) \quad Q_r - Q_s = \sum y_{ij}^2 - \sum (y_{ij} - \hat{y}_i - \hat{y}_i - \hat{y}_i)^2 - \sum \frac{V_i^2}{r_i}.$$

Since 14.5 is the proper statistic for testing the hypothesis $b_i = \mu$ it must have (b-1) degrees of freedom where b is the number of blocks. Moreover it can not depend on the v_i . Thus

$$Q_r - Q_a = \sum_i \sum_i a_{ij} b_i b_i + \sum_i a_i b_i + W.$$

Where W is independent of the b_i and v_i . The a_i , are, moreover, constants and the a_i independent of b_i .

If the b_i are all equal to μ then $\sum_i \sum_j a_{ij}b_ib_j + \sum_i a_ib_i = \mu^2 \sum_i \sum_i a_{ij} + \mu \sum_i a_i$ must be independent of μ and therefore $\sum_i \sum_j a_{ij} = \sum_i a_{ij} = 0$ and $E(W) = (b-1)\sigma^2$. Then

if the b_i are considered as random variables with the expectation μ

$$E(\sum_{i} \sum_{j} a_{ij}b_{j}b_{j} + \sum_{i} a_{i}b_{i})$$

$$= \sigma'^{2} \sum_{i} a_{ii} + \mu^{2} \sum_{i} \sum_{j} a_{ii} + \mu \sum_{i} a_{i}$$

$$= \sigma'^{2} \sum_{i} a_{ii}.$$

Thus the expectation of $Q_r - Q_a$ when the b_i are considered as independent random variables must be of the form $a\sigma'^2 + (b-1)\sigma^2$. To find a we have to find the sum of the coefficients of the b_i^2 appearing in 14.5.

The middle term in 14.5 is an estimate of a multiple of σ^2 and therefore independent of b_i^2 in the first term b_i^2 occurs with the coefficient k_i , in the last term with the coefficient $\sum_{i=1}^{n} 1/r_i$, where $\sum_{i=1}^{n} f(i)$ denotes the summation of f(i) over all i such that the ith variety occurs in the jth block. Hence

(14.6)
$$E(Q_r - Q_a) = \left(N - \sum_i \sum_{j=1}^{(i)} \frac{1}{\tau_i}\right) \sigma^{2} + (b-1)\sigma^{2}$$
$$= (N - v)\sigma^{2} + (b-1)\sigma^{2},$$

where N is the number of experiments and v the number of varieties. Since Q_a has N-v-b+1 degrees of freedom

$$Q_{r} - Q_{a} - \frac{b-1}{N-v-b+1} Q_{a} = Q_{r} - \frac{N-v}{N-v-b+1} Q_{a}$$

may be used as an estimate of $(N - v)\sigma^{2}$.

We shall apply these results to incomplete balanced block designs. The interblock variance σ_B^2 of the block totals becomes

$$\sigma_B^2 = k^2 \sigma'^2 + k \sigma^2.$$

To estimate σ_B^2 we use

$$M = \sum y_{ii}^2 - \sum (y_{ii} - \hat{v}_i - \hat{b}_i + \hat{\mu})^2 - \frac{1}{r} \sum V_i^2$$
,

where \hat{b}_i , \hat{b}_i , $\hat{\mu}$ are given by 7.19. From 14.6 we have

(14.7)
$$E(M) = v(r-1)\sigma^{2} + (b-1)\sigma^{2}$$

Thus putting

$$\frac{Q_a}{bk - v - b + 1} = S^2$$

(14.8)
$$E\left(\frac{kM - (v - k)S^2}{v(r - 1)}\right) = k\sigma'^2 + \sigma^2 = \frac{\sigma_B^2}{k}.$$

1.OLD.IL Thus $k [kM - (v - k)s^2]/[v(r - 1)]$ may be used as an estimate of σ_B^2 . The intrablock estimate of v_i is θ_i = $(kV_i - T_i)/(\lambda v)$. The interblock estimate is found by mini-

(14.9)
$$\text{w.d.dbr} \sum_{j} \text{i.d.}_{xry.ov} \text{fth}^{j} v_{i} = k \mu)^{2}$$

under the restriction $\sum_i v_i = 0$. Differentiation with respect to v_i and μ yields $kr\hat{\mu}' + (r-\lambda)\theta_i' = T_i + \tau, \qquad i = 1, \dots, v,$

$$kr\mu' + (r-\lambda)\vartheta'_i = T_i + \tau, \qquad i = 1, \dots, v,$$

(14.10)

(14.12)

$$\hat{p}' = \frac{\sum y_{ij}}{bk} = y = \hat{\mu}.$$

where τ is the Lagrange operator and \hat{v}_i' , $\hat{\mu}'$ the interblock estimates of v_i , μ . Adding the first of the equations 14.10 over the varieties yields $\tau = 0$ and hence

(14.11)
$$\hat{\theta}_i' = \frac{T_i - kr\hat{\mu}}{r - \lambda}.$$

We shall usually want maximum precision with respect to the estimates of varietal differences. Now

$$\sigma_{\theta_i-\theta_i}^2 = \frac{2k}{\lambda v} \sigma^2,$$

 $\sigma_{i'i-i'i}^2 = \frac{2\sigma_B^2}{(r-\lambda)^2} (r-\lambda) = \frac{2}{(r-\lambda)} \sigma_B^2 .$

Thus maximum precision for the varietal differences is obtained if we use as their estimates the differences of the quantities

$$v_{i}^{*} = \frac{\sigma_{B}^{2}/(r-\lambda)\theta_{i} + (k\sigma^{2})/(\lambda v)\theta_{i}'}{\sigma_{B}^{2}/(r-\lambda) + (k\sigma^{2})/(\lambda v)}$$

$$= \frac{\lambda v\sigma_{B}^{2}\theta_{i} + k(r-\lambda)\sigma^{2}\theta_{i}'}{\lambda v\sigma_{B}^{2} + k(r-\lambda)\sigma^{2}}.$$
The variance of the difference $v_{i}^{*} - v_{i}^{*}$ is given by
$$\sigma_{v_{i}^{*} - v_{i}^{*}}^{2} = \frac{2k\sigma^{2}\sigma_{B}^{2}}{\sigma^{2}k(r-\lambda) + \lambda v\sigma_{B}^{2}}.$$

$$\sigma_{**_{i-v^*_{i}}}^2 = \frac{2k\sigma^2\sigma_B^2}{\sigma^2k(r-\lambda) + \lambda v\sigma_B^2}$$

Thus

$$F=rac{bk-v-b^{\prime}}{1}rac{b^{\prime}}{2k\sigma_{B}^{2}}rac{(v_{i}^{st}-v_{j}^{st})^{2}}{Q_{lpha}}rac{(v_{i}^{st}-v_{j}^{st})^{2}}{Q_{lpha}}$$

has the F distribution with 1 and bk - v - b + 1 degrees of freedom respectively. Actually however σ^2 and σ_R^2 are not accurately known and must be replaced by $Q_a/(bk-v-b+1)$ and

$$k \frac{kM - (v - k)S^2}{v(r - 1)} = S_B^2.$$

This will not lead to a very serious inaccuracy if the number of blocks is sufficiently large. However an advantage is only gained if the soil fertility differences between the blocks is actually very small. Sometimes it may happen that the estimate for σ_B^2 becomes smaller than S^2 . In this case it is recommended to replace it by S^2 in formula 14.13 since $\sigma_B^2 \geq \sigma^2$ under all circumstances and since S^2 is a better estimate of σ^2 than S^2_B even if there are no block differences.

The procedure for utilizing interblock estimates in the analysis of incomplete balanced block designs which we derived above is arranged for easy calculation in the 1943 edition of the statistical Tables of Fisher and Yates.

OTHER DOVER BOOKS ON SCIENCE

```
Abbott, E. A. FLATLAND, Introduction by Banesh Hoffmann, 128pp. 53/4 x 8.
                                                                              11 Paperbound $1.00
Abro, A. d'. THE EVOLUTION OF SCIENTIFIC THOUGHT; from Newton to Einstein. Second
revised and enlarged edition, 21 diagrams, 15 portraits, xx + 481pp, 51s x 8.
                                                                             12 Paperbound $2.00
Abro, A. D'. THE RISE OF THE NEW PHYSICS. Second revised edition. Two volumes. 38
                                                                     13 Vol. | Paperbound $1.95
| T4 Vol. | Paperbound $1.95
portraits, 994pp, 53/8 x 8.
Adams, F. D. THE BIRTH AND DEVELOPMENT OF THE GEOLOGICAL SCIENCES. 79 illustra-
                                                                              15 Paperbound $2.00
tions, 15 full page plates, v + 506pp, 53/8 x 8.
Agricola, G. DE RE METALLICA. Translated by Herbert Hoover and Lou Henry Roover
                                                                             56 Clothbound $10.00
3 indices, 289 illustrations xxxi + 638pp. 634 x 1034.
Archimedes, WORKS, Includes "The Method of Archimedes," Edited by T. L. Healh.
                                                                              SP Paperbound $2.00
clxxxvi + 377pp. 53/8 x 8.
 Bateman, H. THE MATHEMATICAL ANALYSIS OF ELECTRICAL AND OPTICAL WAVE-MOTION
 ON THE BASIS OF MAXWELL'S EQUATIONS, 168pp. 53/8 x 8.
                                                                            St4 Paperbound $1.40
 Baleman. H. PARTIAL DIFFERENTIAL EQUATIONS OF MATHEMATICAL PHYSICS. Index. 29 illustrations. xxii + 52200 6 xxlibrary.org.in 54.75

Bennett, A. A., Milne, W. E., and Bareman, H. NUMERICAL INTEGRATION OF DIFFERENTIAL FOLIATIONS.
 TIAL EQUATIONS, Bibliography, Index, 108pp. 53/a x 8.
                                                                            $305 Paperbound $1.35
 Besicovitch, A. S. ALMOST PERIODIC FUNCTIONS. xiv + 180pp. 53/4 x 8.
                                                                              $17 Clathbound $3.50
                                                                              $18 Paperbound $1,75
 Beyer, R. T. FOUNDATIONS OF NUCLEAR PHYSICS. Facsimiles of 13 basic research papers in the original languages. 122-page bibliography. 56 illustrations. 4 tables. x + 277pp.
                                                                              S19 Paperbound $1.75
 61/8 x 91/4.
  Birkhoff, G. HYDRODYNAMICS; a Study in Logic, Fact, and Similitude. 20 figures. 2 plates. Bibliography, Index. xiv + 186pp. 5% x 8.
                                                                               S21 Clothbound $3.50
                                                                              S22 Paperbound $1.85
  Boss, F. PRIMITIVE ART. 695 illustrations. Name index. 378pp. 5% x 8. 125 Paperbound $1.95
  Bonola, R. NON-EUCLIDEAN GEOMETRY. Authorized English translation with additional
```

appendices by H. S. Carslaw and an introduction by Federigo Enriques. This new edition contains an appendix of the G. B. Halsted translations of Lobachevski's "The Theory of Parallels" and Bolyal's "The Science of Absolute Space." 431pp. 5% x B.

Born, M. THE RESTLESS UNIVERSE. Second revised edition, 120 drawings and figures, 12

Bowen, N. I. THE EVOLUTION OF IGNEOUS ROCKS. New Introduction by J. f. Schairer, Carnegie Institute of Washington. New bibliography. Indices. x + 334pp. 5% \times 8, ca.75

Bragg, W. CONCERNING THE NATURE OF THINGS. 57 figures, 32 plates, 264pp. 53/8 x 8.

Brillouin, L. LES TENSEURS EN MECHANIQUE ET EN ELASTICITE. Text in French, Index.

Brillouin, L. WAVE PROPAGATION IN PERIODIC STRUCTURES. Second ravised edition

Bridgman, P. W. THE NATURE OF PHYSICAL THEORY. Index. xi + 138pp. 53/8 x 8.

Boole, G. LAWS OF THOUGHT, 448pp, 53/8 x 8.

plates. 3 tables, 315pp. 61/8 x 91/4.

144 figures. xx + 364pp. 6 x 9.

index. xii + 259pp. 53/a x 8.

Born, M. EXPERIMENT AND THEORY IN PHYSICS. 44pp. 53/8 x 8.

Findlay, A. THE PHASE RULE AND ITS APPLICATIONS. Revised, enlarged edition brought

Apra University Library
Prono, J. THE KINETIC THEORY OF LIQUIDS. Index. xi , 488pp. 538 x 8. 594 Clathbound \$3.95 59% Paperbound \$1.95 Fry, W. J., Taylor, J. M., and Henvis, B. W. DESIGN OF CRYSTAL VIBRATING SYSTEMS.

Second revised edition, 126 graphs, vivi ; 182pp. 618 x 914. 595 Clathbound \$3.58

Galilei, G. DIALOGUES CONCERNING TWO NEW SCIENCES. Transacted by Henry Crew and Alfonso de Salvio. Introduction by Antonio Favaro. Bibliography. Index. 126 diagrams.

xxi + 300pp. 53 a x 8.SVil Clathbound \$3.50 SPS Paperbound \$1.60

Gaydon, A. G. DISSOCIATION ENERGIES AND SPECTRA OF DIATOMIC MOLECULES. Author index. Subject index. xi + 239pp. 5% x 8. 5101 Clathbound 53.95

5102 Paperbound \$1.60

Gutenberg, B. INTERNAL CONSTITUTION OF THE EARTH, Second revised edition. Bibli-

ography. 43 diagrams, photographs, and graphs. 88 tables. 439pp. 61s x ?!...

SIG4 Clothbound \$5.50

EQUATIONS, Index. v + 316pp. 5% x 8.

Hadamard, J. LECTURES ON CAUCHY'S PROBLEM IN LINEAR PARTIAL DIFFERENTIAL STUD Paperbound \$1.75 TIGG Clothbound \$2.50 TIQ/ Paperbound \$1.25

Hadamard, J. THE PSYCHOLOGY OF INVENTION IN THE MATHEMATICAL FIELD. XII 在 145pp. 53e x 8. Hay, G. E. VECTOR AND TENSOR ANALYSIS, 208pp. 538 x 8. \$107 Paperbound \$1.75

Heath, R. V. MATHEMAGIC; Magic puzzles and games with numbers. 128pp. 548 x 8. 1110 Paperbound \$1.00 Heisenberg, W. THE PHYSICAL PRINCIPLES OF THE QUANTUM THEORY. Translated by C. Eckart and F. C. Hoyt. Index, viii + 184pp. 5% x 8. 5:13 Paperbound \$1.25

Helmholtz, H. L. F. ON THE SENSATIONS OF JONE GNEW 69 illustrations. Index. WWW. GRAPP. introduction by Henry Margenau. Sit4 Clothbound \$4.95 Hertz, H. PRINCIPLES OF MECHANICS. Introduction by Professor Robert S. Cohen, Wesleyan \$314 Clothbound \$3.50 \$317 Paperbound \$1.75 University, 53a x 8.

Herzberg, G. ATOMIC SPECIRA AND ATOMIC STRUCTURE. Translated by J. W. T. Spinks. Second revised edition. Index. 80 illustrations. 21 tables. xv \(\tau \) 257pp. 514 \(\times \)814. S115 Paperbound \$1.95

Hopf, L. INTRODUCTION TO THE DIFFERENTIAL EQUATIONS OF PHYSICS. Translated by Walter Nef. 48 illustrations. vi 4- 154pp. 53/8 x 8.

\$119 Clothbound \$2.50 Si 20 Paperbound \$1.25

Hontington, E. V. THE CONTINUUM; and other Types of Serial Order. Index. 82pp. 538 x B. 5130 Paperbound \$2.75 Ince, E. L. ORDINARY DIFFERENTIAL EQUATIONS, Index, 18 illustrations, viii 4: 558pp-

\$349 Paperbound \$2.45 Jahnke E., and Ende, F. TABLES OF FUNCTIONS WITH FORMULAE and CURVES. (Funktionentatele.) Fourth revised edition. Text in German and English, Index. 212 illustrations.

 $xv + 382pp. 51/2 \times 81/2.$ \$133 Paperbound \$2.00 James, W. THE PRINCIPLES OF PSYCHOLOGY. The Long Course. Two volumes bound as

T134 Clothbound \$7.50 Unabridged, 1408pp, 5% x 8. Jeans, J. THE DYNAMICAL THEORY OF GASES. Fourth revised edition. 444pp. 61/8 x 91/4. \$135 Clothbound \$3.95

S136 Paperbound \$2.00 Jessep, H. T. and Harris, F. C. PHOTOELASTICITY; Principles and Methods. Index. 164 diagrams. vii + 184pp. 616 x 91/4.

Kamke, E. THEORY OF SETS. Translated by F. Bagemini from the second German edition. Bibliography. Index. viii + 152pp. 536 x 8. 5140 Clothbound \$2.75

\$140 Clothbound \$2.75 \$141 Paperbound \$1.35 Kellogg, O. D. FOUNDATIONS OF POTENTIAL THEORY. Index. ix \pm 384pp. 5% x 8. S144 Paperbound \$1.98

Khinchin, A. I. MATHEMATICAL FOUNDATIONS OF STATISTICAL MATHEMATICS. Translated by G. Gamow. Index. viii 4- 179pp. 5% x 8. \$146 Clothbound \$2.95 \$147 Paperbound \$1.35

Klein, F. ELEMENTARY MATHEMATICS FROM AN ADVANCED STANDPOINT; Algebra, Arithmetic, Analysis, Translated from the third German edition by
